The synthesis of starch, cellulose, inulin, gum, &c., is only a question of time, and, judging from the great strides which have been made in organic synthesis during the last 62 years, the chemist need have no hesitation in attempting to prepare synthetically any product whatever of the living organism. F. S. K.

Sugars Richer in Carbon, from d-Mannose. By E. Fischer and F. Passmore (*Ber.*, **23**, 2226—2239).—d-Mannose, which can be prepared in large quantities from vegetable ivory-nuts (compare Fischer and Hirschberger, this vol., p. 224), can be more readily converted into the carboxylic acid by means of hydrocyanic acid than the other natural sugars. It has, therefore, been employed for the synthesis of some higher sugars in the manner described below; as the compounds produced all crystallise well, the authors have experienced no difficulties in continuing the process up to the formation of the compound $C_9H_{18}O_9$. The sugars obtained in this way are named d-mannoheptose, d-mannooctose, and d-mannononose, in accordance with the system of nomenclature already proposed (this vol., p. 598), the corresponding acids being termed d-manno-heptonic, -octonic, and -nononic acids respectively, and the alcohols, heptitol and octitol. All these compounds contain a normal chain of carbon-atoms, and the three synthetical sugars are all aldehydes.

d-Mannoheptonic acid, $C_7H_{14}O_8$ (previously called mannosecarboxylic acid, compare Abstr., 1889, 482), is prepared by heating ivory-nut shavings with hydrochloric acid as already described (this vol., p. 224), neutralising the filtered solution with lead carbonate, precipitating the lead with sodium carbonate, and evaporating the solution of mannose (2 kilos.), obtained in this way, to a syrup. The syrup is dissolved in water (4 parts), treated, in eight separate portions, with the theoretical quantity of hydrocyanic acid and a few drops of ammonia, the mixture kept for three days at the ordinary temperature, then heated at 50° for four hours, and barium d-mannoheptonate prepared from it in the manner already described (Abstr., 1889, 482); the weight of the pure salt thus obtained is about the same as that of the sugar employed. The barium salt is then dissolved in hot water (10 parts), the base exactly precipitated with sulphuric acid, the filtrate decolorised with animal charcoal, and evaporated; the crystalline residue consists of a mixture of mannoheptonic acid and its lactone, from which the acid can be isolated in a pure condition by recrystallising several times from hot water.

d-Mannoheptonic acid melts at 175°, being converted into the lactone, the same change occurring when it is heated at 130°, and also (but only partially) when it is kept over sulphuric acid, or boiled with water or alcohol. It is soluble in 25 parts of water at 30°, the solution being feebly levo-rotatory. The *sodium* salt, $C_7H_{13}O_8Na$, crystallises in long needles, melts at 220—225°, and is rather sparingly soluble in cold water. The lactone (Abstr., 1889, 482) has a sweet taste, and its specific rotatory power is $[\alpha]_{D20} = -74\cdot23$.

d-Mannoheptose, $C_7H_{14}O_7$, is obtained as follows:—The pure lactone (10 grams) is dissolved in water (100 c.c.), mixed with 20 per cent. sulphuric acid (1 c.c.), the solution cooled to its freezing point, and $2\frac{1}{2}$ per cent. sodium amalgam (120 grams) added in the course of 30 to 40 minutes, the whole being vigorously shaken and kept acid by the frequent addition of dilute sulphuric acid; the decanted solution is now mixed with soda in such quantity that it remains slightly alkaline after keeping for 15 minutes, so as to convert any unchanged lactone into the sodium salt of the acid; the filtered solution is then exactly neutralised with sulphuric acid in the cold, evaporated at 100° until crystallisation commences, and poured into boiling absolute alcohol (10 parts). The precipitated sodium salts are redissolved in hot water, again precipitated with alcohol, and the alcoholic mother liquors from the two operations evaporated, when the sugar remains as a syrup which crystallises after one to two days' time; the yield is, on the average, 40 per cent. of the lactone employed.

The compound prepared in this way still contains a little inorganic matter and small quantities of the heptahydric alcohol, but it can be directly employed for the synthesis of the higher sugars. About half the lactone is converted into mannoheptonic acid in the reduction process, and is recovered in the form of the sodium salt, mixed, however, with sodium sulphate; this mixture is dissolved in the least possible quantity of hot water, the solution cooled, and excess of dilute sulphuric acid added before crystallisation commences; after remaining for a long time most of the heptonic acid is deposited in crystals.

The crude mannoheptose, prepared in the manner described, can be freed from ash by recrystallisation from 96 per cent. alcohol, but it still contains heptitol (see below), from which it cannot be separated, except by converting it into the hydrazone. This compound is gradually precipitated in crystals when phenylhydrazine acetate is added to a cold aqueous solution of the crude sugar, and can be obtained in a pure state by recrystallisation from hot water. It is dissolved in fuming hydrochloric acid (4 parts), the solution kept for 15 minutes at 20°, then cooled well, filtered, the filtrate diluted, neutralised with lead carbonate, the filtered solution rendered alkaline with barium hydroxide, and shaken with ether until free from phenylhydrazine. The residual solution is then treated with a slight excess of sulphuric acid, freed from hydrochloric acid and sulphuric acid in the usual manner, shaken with animal charcoal until colourless, evaporated under reduced pressure, and the residual syrup, which soon solidifies when covered with alcohol, recrystallised from this solvent; the yield of pure sugar is 39 per cent. of the hydrazone employed.

d-Mannoheptose crystallises in slender needles, melts at 134—135° (corr.) to a coloured liquid, turns brown at about 190°, has a sweet taste, and is very readily soluble in water, but only very sparingly in boiling alcohol; it seems to crystallise from dilute methyl alcohol with 1 mol. H_2O. Its specific rotatory power, 10 minutes after solution, is $[\alpha]_{D20} = 85{\cdot}05$, but it gradually decreases, and, after 24 hours, has become constant, being then $[\alpha]_{D20} = 68{\cdot}64$. It gives all the usual reactions of sugars, and, like d-mannose, it is precipitated from its aqueous solution by basic lead acetate. When yeast is placed in a 10 per cent. aqueous solution of the sugar, kept at 30°, no fermentation takes place in the course of 24 hours.

The *hydrazone*, $C_7H_{14}O_6{:}N_2HPh$, crystallises from hot water in slender, colourless needles, melts at 197—200° with decomposition when quickly heated, and is only very sparingly soluble in cold water. Its freshly-prepared solution in fuming hydrochloric acid, diluted with water, is optically inactive, but in 45 minutes it shows a dextrorotation of 0·45°; in this respect it differs from the sparingly soluble hydrazones of d- and l-mannose.

d-Mannoheptosazone, $C_7H_{12}O_5(N_2HPh)_2$, separates in slender needles, when an aqueous solution of the hydrazone is heated with phenylhydrazine acetate. It crystallises from hot alcohol in slender needles, melts with decomposition at about 200°, when quickly heated, and is very sparingly soluble in hot alcohol, and almost insoluble in water and ether; its solution in glacial acetic acid is dextro-rotatory.

Heptitol (perseitol), $C_7H_{16}O_7$, is obtained when mannoheptose is reduced with sodium amalgam as described in the preparation of mannose (this vol., p. 466); the yield is about 70 per cent. of the sugar employed. A direct comparison of this synthetical alcohol with perseitol, which has been shown by Maquenne (Abstr., 1889, 32) to be a heptahydric alcohol, proved the identity of the two compounds, as does also the fact that Maquenne's perseitol, on oxidation with nitric acid of sp. gr. 1·14, is converted into mannoheptose.

d-Mannoctonic acid can be prepared from crude crystalline mannoheptose by treating it with hydrocyanic acid and a few drops of ammonia, as described in the preparation of the heptonic acid; as the barium salt does not crystallise well, the acid is best purified by heating its dilute aqueous solution with phenylhydrazine and acetic acid. The *hydrazide*, $C_8H_{15}O_8{\cdot}N_2H_2Ph$, which is gradually deposited from the solution, crystallises from hot water in colourless needles melting at about 243° with decomposition when quickly heated: it is almost insoluble in cold water and alcohol, and rather sparingly soluble in hot water. It is reconverted into the acid by boiling with barium hydroxide, as previously described (this vol., p. 153), but the acid was not isolated; the solution, freed from barium hydroxide and phenylhydrazine, and decolorised with animal charcoal, is evaporated, and the residual mannoctolactone, which gradually solidifies when treated with alcohol, purified by recrystallisation from this solvent. 30 grams of mannoheptose yield 19 grams of the pure lactone.

Mannoctolactone, $C_8H_{14}O_8$, melts at about 167—170° with decomposition, has a sweet taste, and is very readily soluble in water, the solution becoming slightly acid after some time; it dissolves rather freely in hot alcohol, and its specific rotatory power is $[\alpha]_{D20} = -43{\cdot}58$.

d-Mannoctose is obtained from the lactone (1 part) exactly as described in the case of mannoheptose, except that a larger quantity (16 parts) of $2\frac{1}{2}$ per cent. sodium amalgam is required; on evaporating its alcoholic solution, there remains a sweet syrup, which does not crystallise even when purified by means of the hydrazone. It is very readily soluble in water, only very sparingly in absolute alcohol, is levo-rotatory, and does not ferment with yeast. The *hydrazone*, $C_8H_{16}O_7{:}N_2HPh$, crystallises from hot water, in which it is sparingly soluble, in colourless needles, and melts, when quickly heated, at about 212° with decomposition. The *osazone*, $C_8H_{14}O_6(N_2HPh)_2$, is gradually deposited in yellow needles when a dilute aqueous solution of the sugar, or of the hydrazone, is warmed with excess of phenylhydrazine acetate; it is almost insoluble in hot water and boiling alcohol, and melts at about 223° with decomposition.

d-*Mannoctitol*, $C_8H_{18}O_8$, prepared from the sugar by reducing it with sodium amalgam as described under mannoheptose, separates from hot water, in which it is only moderately easily soluble, in colourless, microscopic plates, sinters together at 250°, and melts completely at 258°; when heated in small quantities, it volatilises without leaving any carbonaceous residue.

d-*Mannononic lactone*, $C_9H_{16}O_9$, can be obtained by treating mannoctose with hydrocyanic acid, converting the product into the hydrazide of mannononic acid, and decomposing the latter with barium hydroxide exactly as described in the case of the lower homologue; on evaporating the aqueous solution of the acid to a syrup, it is almost completely converted into the lactone, which, when treated with alcohol, gradually solidifies. It crystallises from hot alcohol in slender needles, melts at 175—177°, and is readily soluble in water, and moderately easily in hot alcohol; it has a sweet taste, and its specific rotatory power is $[\alpha]_{D20} = -41°$.

d-*Mannononose*, $C_9H_{18}O_9$, can be obtained from the lactone without difficulty by the same method as that employed in the preparation of mannoctose; it separates from hot alcohol in small nodules, but it has not yet been obtained free from ash, sufficient material not having been prepared to allow of its purification by means of the hydrazone. It melts at about 130°, and is dextro-rotatory. The *hydrazone*, $C_9H_{18}O_8{:}N_2HPh$, crystallises from hot water in colourless needles, melts at about 223° with decomposition when quickly heated, and is very sparingly soluble in cold water. The *osazone* crystallises in yellow needles, melts at about 217° with decomposition, and is almost insoluble in hot water and alcohol.

Mannononose ferments with yeast just as readily as mannose and grape-sugar, carbonic anhydride being evolved, and a solution obtained which has an odour of alcohol, and which gives the iodoform reaction very distinctly. It is a curious fact that most of the sugars, such as glycerose, the hexoses, and mannononose, which contain three, or a simple multiple of three, carbon-atoms ferment with yeast, whereas the pentoses (arabinose and xylose), mannoheptose, and mannoctose do not.

Mannononose resembles dextrose so closely that the two compounds can be easily mistaken for one another; they have, moreover, the same percentage composition, approximately the same rotatory power, almost the same melting point, and both ferment with yeast, so that if mannononose had been obtained from the vegetable kingdom before the hydrazone test was known, it would certainly have been mistaken for dextrose. The occurrence of mannononose in plants would not be surprising, because it is more than probable that glyceraldehyde is formed in the vegetable kingdom; this compound so easily condenses to hexoses that it seems likely that, under other conditions, it might undergo condensation to mannononose.

The optical behaviour of the compounds described above is worthy of note, the rotatory power changing in an irregular manner from right to left and *vice versâ*, as is shown by the following table:—

d-Mannose Series.

Hexonic lactone..	+53·81°	Octonic lactone..	−43·58°
Hexose	+12·96	Octose	−3·3 (approx.).
Heptonic lactone.	−74·23	Nononic lactone .	−41·0
Heptose	+85·05	Nonose	+50·0 (approx.).

F. S. K.

The Sulphines and the Different Valencies of Sulphur. By R. NASINI and A. SCALA (*Gazzetta*, 19, 526—528).—This is a paper of a polemical character containing a reply to Klinger and Maassen (Abstr., 1888, 357; 1889, 1135). The authors maintain that the measurements given by them and La Valle (Abstr., 1889, 115) fully establish the isomerism of the platinochlorides of diethylmethylsulphine and ethylmethylethylsulphine, the former crystallising in the cubic, and the latter in the monoclinic system as stated by Krüger (Abstr., 1877, 186). S. B. A. A.

Myristic Aldehyde. By F. KRAFFT (*Ber.*, 20, 2360—2364; compare Abstr., 1889, 1017).—Tetradecyl alcohol, $C_{13}H_{27}\cdot CH_2\cdot OH$, is obtained by reducing myristic aldehyde with sodium in alcoholic solution. The *hydrogen sodium sulphite* compound, $C_{14}H_{29}O\cdot SO_3Na$, is prepared by heating myristic aldehyde with a saturated aqueous solution of hydrogen sodium sulphite at 55°; it crystallises from alcohol in colourless plates, and slowly decomposes at 130° without melting. The corresponding *potassium* compound is very similar in properties. *Tetradecylaldoxime*, $C_{13}H_{27}\cdot CH{:}NOH$, is obtained by treating the aldehyde with half its weight of hydroxylamine hydrochloride in alcoholic solution; it crystallises from alcohol in silvery, lustrous plates melting at 82°, and has a slight peppermint-like odour. *Tetradecylamine*, $C_{14}H_{24}\cdot NH_2$, is formed by the reduction of the aldoxime with sodium amalgam in alcoholic solution, to which acetic acid is added from time to time; it melts at 37°, boils at 162° under a pressure of 15 mm., and is most readily purified by distillation; it rapidly absorbs carbonic anhydride on exposure to air. The same compound may also be obtained by reducing myristonitrile, $C_{14}H_{27}N$, with sodium in alcoholic solution. The *hydrochloride*, $C_{14}H_{29}\cdot NH_2,HCl$, is readily soluble in water; it crystallises from ether in lustrous plates, which decompose on heating. The *platinochloride* has also been prepared. *2′-Tridecylquinoline*, $C_9H_8N\cdot C_{13}H_{27}$, is formed by the distillation of the product obtained by the action of aniline and pyruvic acid on tetradecylaldehyde. It crystallises in large. white plates melting at 31—32°. The *hydrochloride* and *platinochloride* have been prepared; the latter crystallises in yellow, lustrous plates. *Dodecylamine*, $C_{12}H_{25}\cdot NH_2$, is formed by the reduction of lauronitrile with sodium in alcoholic solution; it melts at 27—28°, and boils at 134—135° under a pressure of 15 mm. (compare Lutz, Abstr., 1886, 685). J. B. T.

Reduction-products of 1 : 2-Diketones. By H. v. PECHMANN and F. DAHL (*Ber.*, 23, 2421—2427; compare Abstr., 1889, 1137).—Dimethylketol, $COMe\cdot CHMe\cdot OH$, is prepared by warming diacetyl

(20 grams) with granulated zinc (30 grams), and dilute (1 : 5) sulphuric acid (280 grams); the product is extracted 20 times with ether, the ether cautiously evaporated, and the residue dried over anhydrous sodium sulphate. The yield is quantitative; the ketol boils at 141—142°, has a sp. gr. of 1·0021 at 15°/4°, and is miscible with all the ordinary solvents except light petroleum. It reduces Fehling's solution, and is readily oxidised on exposure to air. The *phenylhydrazone*, $CHMe(OH)\cdot CMe{:}N_2HPh$, is obtained by treating a mixture of the ketol and phenylhydrazine, in molecular proportion, with sodium acetate in aqueous solution; it separates as an oil, which solidifies on cooling. It crystallises from benzene, on the addition of light petroleum, in stellate groups of long prisms melting at 83—84°. It is readily soluble in alcohol, ether, chloroform, benzene, and dilute acids, but not in alkalis; it quickly undergoes decomposition on keeping. With excess of phenylhydrazine in the cold, the ketol yields a mixture of diacetylphenylhydrazone and diacetylosazone; the latter is also formed on warming the ketol with excess of phenylhydrazine. Dimethylketol does not solidify in a freezing mixture, but if allowed to remain for several weeks, or months, it becomes converted into a solid crystalline modification melting at 127—128°; the addition of a crystal of this compound to the liquid ketol does not hasten its solidification. A second solid modification is obtained by adding some indifferent substance, such as a piece of granulated zinc, to the liquid ketol; in a few hours it crystallises in colourless, thin plates melting at 96—98°; after some time the crystals liquefy spontaneously at ordinary temperatures, and then gradually pass into the modification of high melting point. These two substances are quite distinct, they may be sublimed without change by cautiously heating; they dissolve slowly in ordinary solvents, becoming converted into the liquid ketol, which is also formed by distilling, or melting, either of them. Both are optically inactive, but it appears probable that they are physical, rather than chemical, isomerides.

Methylethylketol, $COMe\cdot CHEt\cdot OH$, is prepared from acetylpropionyl; it is a colourless, sweet-smelling liquid, closely resembling the dimethyl-derivative in properties; it boils at 152—153°, and at 77° under a pressure of 35 mm.; its sp. gr. is 0·9722 at 17·5°/4°. On treatment with phenylhydrazine, the *phenylhydrazone* is formed. With excess of phenylhydrazine in the cold, acetylpropionyl-α-phenylhydrazone, $COEt\cdot CMe{:}N_2HPh$, is obtained, thus showing the constitution of the ketol. δ-Methylethylethylene glycol, $CHMe(OH)\cdot CHEt\cdot OH$, is prepared by reducing methylethylketol with sodium amalgam; it is identical with the compound obtained by Wagner and Saytzeff from δ-methylethylethylene bromide (compare Abstr., 1876, 547).

J. B. T.

Isophorone. By W. F. Laycock (*Annalen*, **258**, 230—234; compare Abstr., 1889, 487).—The higher boiling (115—150°) fractions of the oil obtained by distilling sugar with lime contain a considerable quantity of a mixture of ketones, probably the compounds $C_5H_{10}O$ and $C_6H_{12}O$, which can be separated from the other constituents of the oil by shaking with sodium hydrogen sulphite. The residue contains a new furfuraldehyde-derivative, the presence of which can be proved as follows:—The oil is treated with phenylhydrazine, kept for some hours, the excess of phenylhydrazine removed by washing with dilute acetic acid, and the residual solution distilled with steam; the oil that passes over is fractionated, and the portion boiling between 115 and 130° is heated at 170° with concentrated hydrochloric acid, whereby the furfuraldehyde-derivative is converted into a 1.4-diketone. This diketone has the composition $C_7H_{12}O_2$, and boils at 197—200°; it does not give the aldehyde reactions, and it yields a pyrroline-derivative when boiled with ammonium acetate. The *dioxime*, $C_7H_{14}N_2O_2$, melts at 129° and is readily soluble in hot, but only sparingly soluble in cold water. The constitution of the ketone is represented by one of the formulæ

$$COMe{\cdot}CHMe{\cdot}CH_2{\cdot}COMe \text{ or } COEt{\cdot}CH_2{\cdot}CH_2{\cdot}COMe.$$

The presence of isophorone in the other fractions of the oil could not be detected; the compound described under this name by Benedikt (*Annalen*, **162**, 306) is evidently a mixture of various substances. F. S. K.

Electrolysis of Fatty Acids. By N. BUNGE (*J. Russ. Chem. Soc.*, **21**, 525—557).—Referring to the work done previously by Kolbe, Kolbe and Kaempf, Brazier and Gossleth, Wurtz, Schorlemmer and Kekulé, the author considers the reaction a very complicated one, which cannot be represented by a simple chemical equation. The author's own earlier experiments with oxalic, formic, and mellitic acids have convinced him that Kekulé's general formulæ:

$$C_nH_{2n}(COOM)_2 = M_2 + 2CO_2 + C_nH_{2n} \text{ and}$$
$$2C_nH_{2n+1}{\cdot}COOM = M_2 + 2CO_2 + (C_nH_{2n+1})_2$$

are not in accordance with facts, and that the complicated groups set free at the anode are not decomposed into their simpler constituents, but that they enter into reaction with water, re-forming the original acid and oxygen, and that the latter, on being liberated, oxidises the electrolyte, and thus forms the different products.

The original paper contains a detailed description of the author's apparatus, the preparation of *pure* substances, and a large set of tabularly arranged analytical data of the gaseous products. It is shown also, that the nature and relative quantity of the products obtained at the anode vary very considerably with varying concentration, intensity of the current, size and surface of electrodes, and especially with the temperature of the electrolyte.

Potassium propionate yielded, besides carbonic anhydride and hydrogen, a large proportion of ethylene, and only a small quantity of butane, although the latter ought to be the chief product, if Kekulé's view were correct. As regards oxygen, this gas was not observed at 0°, but at 100° the quantity was much larger than that of the hydrocarbons. No definite relation could be traced between the quantities of ethylene and butane. *Free propionic acid* yielded very nearly the same product as its potassium salt. *Isobutyric acid*, when submitted to electrolysis at 0°, gave not the expected hexane, but only carbonic anhydride, propylene, hydrogen, and oxygen, and at 100° scarcely any hydrocarbon. *Normal butyric acid* yielded propylene as the chief product, together with some butane, and a trace of a liquid hydrocarbon, probably hexane.

In order to test the correctness of Kolbe's and Kaempf's statement that acetic acid yields ethylene on electrolysis, the author prepared *pure* sodium acetate with the greatest care, and passed the products of electrolysis for 48 hours through bromine, but not a trace of ethylene bromide could be found. In all cases, the acids yielded small quantities of ethereal salts. The author remarks that india-rubber corks and joints are to be avoided in this kind of work, as a considerable absorption of hydrocarbons takes place, the india-rubber swelling up. In conclusion, the author says that the above view on the complexity of the chemical process in electrolysis, as first pronounced by Bourgoni, is entirely confirmed. B. B.

Oxidation of Cerotic Acid by Nitric Acid. By T. MARIE (*J. Pharm.* [5], 22, 145—150).—When cerotic acid is oxidised with nitric acid of above 1·3 sp. gr., succinic acid is the chief product; the reaction is very violent, and the intermediate products are destroyed. Nitric acid of 1·15 sp. gr. gives much better results. After 48 hours' boiling, the cooled mass consists of a liquid and a superposed solid; these were examined separately. As the yield of acid formed by oxidation is only small, the products of 18 operations were united and examined together. The liquid contains the volatile acids caproic, valeric, acetic, and butyric; and the non-volatile acids sebacic, succinic, suberic, pyrotartaric, and probably adipic. The insoluble portion well washed and treated on the sand-bath with very dilute baryta-water yields soluble and insoluble barium salts which have the composition of the caprate, caprylate, and œnanthylate. The insoluble barium salts contained the undecomposed cerotic acid, and a nitro-derivative of cerotic acid whose lead salt is insoluble in ether.

J. T.

Decamethylenedicarboxylic Acid. By H. NOERDLINGER (*Ber.*, 23, 2356—2359).—*Methyl undecylenate*, $C_{10}H_{19}\cdot COOMe$ is a colourless liquid, insoluble in water; it boils at 248° under a pressure of 760 mm., and at 124° at 10 mm. *Ethyl undecylenate*, $C_{10}H_{19}\cdot COOEt$ resembles the methyl compound, and boils at 259° under a pressure of 760 mm., and at 131·5° at 10 mm. *Methyl bromundecylenate*, $C_{10}H_{20}Br\cdot COOMe$, is prepared from methyl undecylenate by treatment with hydrobromic acid; it is a colourless, strongly refractive liquid, boiling at 165·5° under a pressure of 10 mm. *Ethyl bromundecylenate*, $C_{10}H_{20}Br\cdot COOEt$, is obtained in a similar manner to the methyl-derivative; it boils at 171—172° under a pressure of 10 mm. In order to prepare *decamethylenedicarboxylic* acid, $C_{10}H_{20}(COOH)_2$, either of the above brominated compounds is treated with potassium cyanide, and the product hydrolysed with alcoholic potash; on adding hydrochloric acid, a precipitate is formed consisting of a mixture of several acids; this is distilled, and the portion boiling above 230° under a pressure of 10 mm. is dissolved in ammonia. On adding barium chloride, the barium salt separates, and, from this, the pure acid may be obtained. It crystallises from water in slender, flat, lustrous needles, melting at

124·5—125·5°, and boiling at 245° under a pressure of 10 mm.; it is soluble in 891 parts of water at 100°, and in 22,225 parts at 23°. In its chemical and physical properties the acid is completely analogous to the lower homologues of the oxalic acid series. The *potassium*, *sodium*, and *ammonium* salts are soluble in water. All the remaining salts are sparingly soluble in cold water, and are deposited on warming the solution. The *silver* salt is obtained as a white powder, which becomes violet on exposure to light. J. B. T.

Haloïd Derivatives of Ethyl Acetoacetate. By A. HANTZSCH (*Ber.*, **23**, 2339—2342).—On treating ethyl acetoacetate with bromine, ordinary ethyl bromacetoacetate is formed, from which *ethyl amidothiazylacetate*,  $\mathrm{NH_2\cdot C}\Big\langle\begin{array}{l}\mathrm{S\cdot CH}\\ \mathrm{N\cdot C\cdot CH_2\cdot COOEt}\end{array}$, and *ethyl methylthiazylacetate*, $\mathrm{MeC}\Big\langle\begin{array}{l}\mathrm{S\cdot CH}\\ \mathrm{N\cdot C\cdot CH_2\cdot COOEt}\end{array}$, are prepared by the action of thiocarbamide and thioacetamide respectively. These compounds are isomeric with the corresponding thiazole-derivatives obtained from ethyl chloracetoacetate which are represented by the formulæ,  $\mathrm{NH_2\cdot C}\Big\langle\begin{array}{l}\mathrm{S\cdot C\cdot COOEt}\\ \mathrm{N\cdot CMe}\end{array}$, and $\mathrm{MeC}\Big\langle\begin{array}{l}\mathrm{S\cdot C\cdot COOEt}\\ \mathrm{N\cdot CMe}\end{array}$. Ethyl bromacetoacetate, prepared by the action of bromine on ethyl cupracetoacetate (compare Schönbrodt, this vol., p. 27), yields compounds identical with those obtained from the chloracetoacetate. It appears, therefore, that by the direct action of bromine on ethyl acetoacetate, the γ-derivative, $CH_2Br\cdot CO\cdot CH_2\cdot COOEt$, is formed, and that Schönbrodt's compound is really the α-derivative, $CHBrAc\cdot COOEt$, corresponding with the well-known chlorinated derivative. Ethyl methacetoacetate yields a γ-bromo-substitution product which combines with thiacetamide, and, after elimination of the carboxyl-group, forms *methylethylthiazole*, $\mathrm{MeC}\Big\langle\begin{array}{l}\mathrm{S\cdot CH}\\ \mathrm{N\cdot CEt}\end{array}$. Chlorine, however, gives the α-derivative, from which *trimethylthiazole*, $\mathrm{MeC}\Big\langle\begin{array}{l}\mathrm{S\cdot CMe}\\ \mathrm{N\cdot CMe}\end{array}$, is obtained by the action of thiacetamide. J. B. T.

Action of Alcoholic Potash on Bromisosuccinic Acid. By S. TANATAR (*J. Russ. Chem. Soc.*, **21**, 558—563).—Isosuccinic acid, prepared from ethyl α-bromopropionate, is treated with bromine at 100° to convert it into the dibromopropionic acid melting at 118—119°. This is boiled for four to five hours with alcoholic potash, the alcohol removed by distillation, and the residue acidified with hydrochloric acid, after which the liquid is extracted with ether. On distilling off the ether, an oil is left, which after some time becomes converted into a crystalline mass consisting of a mixture of two or three acids. The cold aqueous solution of these is saturated with milk of lime, and after some time filtered from the excess of lime and from the sparingly soluble calcium salt of an acid having the formula $C_8H_{10}O_9$.

The filtrate on being acidified with a few drops of hydrochloric and acetic acids and boiled, deposits a copious precipitate consisting of a calcium salt of one of the acids. This is purified by dissolving it in cold water and heating the solution, when it is again deposited. Its composition is $C_6H_8CaO_5$. The zinc salt is also more soluble in cold than in hot water. The silver salt has the formula $C_6H_8Ag_2O_5$. The acid itself, *adipomalic acid*, $C_6H_{10}O_5$, when crystallised from water or ether is deposited in small, glistening needles, which melt at 111°. At 150—160°, the acid is decomposed into carbonic anhydride and an oily acid, $C_5H_{10}O_3$, which the author considers to be β-hydroxyvaleric acid.

B. B.

Ethyl Oximidosuccinates. By A. PIUTTI (*Chem. Centr.*, 1890, i, 938—939; from *Ann. Chim. Farm.*, **11**, 161).—Of the three possible monethyl oximidosuccinates, the α-salt has been already described (Abstr., 1885, 1122), and also by the author the γ-salt (Abstr., 1889, 383), but the β-salt, COOH·C(NOH)·CH_2·COOEt, is still unknown. The author finds that diethyl oximidosuccinate is identical with the oxime of ethyl oxalacetate, and that the α-ethyl oximidosuccinate is converted into the γ-salt by the action of sodium ethoxide.

J. W. L.

Diacetamide. By W. HENTSCHEL (*Ber.*, 23, 2394—2401).—Diacetamide is best prepared by boiling acetamide (600 grams) with acetic anhydride (1250 grams) for half an hour in a reflux apparatus. The addition of sodium acetate is needless. The product is distilled, and the portion boiling below 125° is fractionated under a pressure of 10 mm.; the greater part passes over at about 108—109°; it is dissolved in 10 parts of pure ether, and the acetamide precipitated with gaseous hydrogen chloride; on cooling the clear solution, diacetamide separates in slender, white needles. This may be purified either by repeated recrystallisation from ether, or by moistening with water, adding barium carbonate, and evaporating nearly to dryness on the water-bath; the residue is then completely dried in a vacuum, and extracted with ether; on evaporation, pure diacetamide separates; it melts at 77·5—78°, and boils at 222·5—223·5°, not at 210—215° as stated by Gautier; under a pressure of 10 mm., the boiling point is 108—108·5°. Diacetamide burns with a non-luminous flame. On heating at 250° for two hours in a sealed tube, acetonitrile, acetic acid, and acetamide, together with unchanged diacetamide, are obtained. The reactions which take place are somewhat complicated; acetonitrile and acetic acid are first formed, but at higher temperatures these recombine; part of the acetic acid, however, acts on the diacetamide yielding acetamide. An aqueous solution of diacetamide is neutral, but becomes acid on prolonged boiling; the decomposition proceeds uniformly; after two hours' heating at the boiling point of methyl alcohol, 7·3 per cent. of the diacetamide is decomposed, after 12 hours' heating 43 per cent.; the products are acetic acid and acetamide. With mineral acids the decomposition proceeds very much more rapidly, ammonium salts being also formed. Concentrated sulphuric acid readily acts on diacetamide with production of acetic acid; with nitrous acid it yields ammonium nitrate and acetic acid. Neither acetic anhydride nor ammonia gas reacts with diacetamide; potassium hydroxide hydrolyses it to acetic acid and acetamide; the same result is obtained with sodium ethoxide. *Sodium diacetamide*, $NNaAc_2$, may be prepared by warming sodium with an anhydrous ethereal solution of pure diacetamide for 10 to 12 hours; it forms a very hygroscopic, white powder. Methylacetamide is obtained by heating the sodium compound with methyl iodide in a sealed tube at 120°. Triacetamide is formed by heating sodium acetamide with acetic chloride or anhydride, diluted with ether or benzene; it is separated by distillation and appears to boil at 93—94° under a pressure of 14 mm.; it solidifies on cooling, but is a liquid at ordinary temperatures, thus differing in a very marked manner from the compound (m. p. 77—78) which has hitherto been regarded as being triacetamide. J. B. T.

Condensation of Carbamide with Ethyl Acetoacetate. By R. BEHREND and P. ERNERT (*Annalen*, **258**, 360—362).—Ethyl sodioacetoacetate and carbamide combine together in alcoholic solution, yielding a colourless, crystalline compound of the composition $C_{13}H_{22}N_2O_7Na_2$. This substance melts at about 165°, and crystallises unchanged from hot alcohol, but is decomposed by water; when dry it is not acted on by carbonic anhydride, but the moist substance is rapidly decomposed. On passing carbonic anhydride into its alcoholic solution, it is decomposed into carbamide, ethyl acetoacetate, and sodium ethyl carbonate, and when boiled with methyl iodide in alcoholic solution, it yields carbamide and ethyl acetoacetate, together with sodium iodide. F. S. K.

Diazouracilcarboxylic Acid and its Derivatives. By R. BEHREND and P. ERNERT (*Annalen*, **258**, 347—359; compare Abstr., 1888, 809).—*Diazouracilcarboxylic acid*,  $\begin{matrix}CO\cdot NH\cdot C\cdot COOH\\ | \qquad\qquad \| \\ NH\cdot CO\cdot C\cdot N{:}NOH\end{matrix}$, is deposited in needles containing water of crystallisation when amidouracilcarboxylic acid is digested with sodium nitrite and water, and the ice-cold, filtered solution acidified with hydrochloric acid. It is readily soluble in alkalis, but only sparingly in water, to which it imparts an acid reaction; when an aqueous solution is heated at 40—50° carbonic anhydride is evolved, and the solution turns purple, but on boiling, nitrogen is given off, and a yellow, amorphous substance is deposited on cooling. It is unstable, and when kept for a long time at the ordinary temperature it is converted into diazouracil.

Hydrazineuracilcarboxylic acid, $C_5H_6N_4O_4$, is obtained when the preceding compound is reduced with hydrochloric acid and stannous chloride in ice-cold aqueous solution; hydroxylamine is not formed in the reaction. It separates from hot 8 per cent. hydrochloric acid in ill-defined crystals, gradually decomposes at 100°, turns brown at 120°, and is insoluble in cold but soluble in hot water, yielding a red solution; it reduces Fehling's solution in the cold, and its constitution is probably expressed by the formula  $\begin{matrix}CO\cdot NH\cdot C\cdot COOH\\ | \qquad\qquad \| \\ NH\cdot CO\cdot C\cdot NH\cdot NH_2\end{matrix}$.

A compound of the composition $C_6H_8N_4O_3$ $(= C_4H_2N_4O_2,C_2H_6O)$

is formed with evolution of carbonic anhydride when freshly-prepared diazouracilcarboxylic acid is boiled with alcohol; it crystallises from alcohol in yellow plates, loses 1 mol. of alcohol at 100°, and explodes when heated on platinum foil. It is almost insoluble in cold alcohol, ether, and hot water, and it is decomposed by boiling water, potash, and hydrochloric acid.

A salt of the composition $C_4H_3N_4O_3K$ is formed when the preceding compound is agitated with the theoretical quantity of cold 1 per cent. potash; it crystallises in needles, is only sparingly soluble in water, and is decomposed by alcohol and alkalis.

Diazouracil, $C_4H_4N_4O_3$. is obtained when the salt just described is suspended in ice-cold water, and decomposed with concentrated hydrochloric acid, also when the compound of the composition $C_6H_8N_4O_3$ is boiled with water. It separates from hot water in crystals, is decomposed by warm dilute acids with evolution of nitrogen, and explodes when heated on platinum foil.

Hydrazineuracil hydrochloride, $C_4H_6N_4O_2,HCl$, prepared by reducing the compound of the composition $C_6H_8N_4O_3$ with stannous chloride and hydrochloric acid in well-cooled aqueous solution, crystallises in colourless plates, and is decomposed by boiling water; it reduces Fehling's solution in the cold, and when treated with sodium carbonate or acetate it yields yellow or reddish compounds, which seem to be decomposition-products of the base. The constitution of the base may be expressed by the formula  $\begin{array}{l} CO{\cdot}NH{\cdot}CH \\ \vert \qquad\quad\ \Vert \\ NH{\cdot}CO\ C{\cdot}NH{\cdot}NH_2 \end{array}$.

F. S. K.

Derivatives of Diethylthiocarbamide. By G. Noah (*Ber.*, 23, 2195—2200).—*Methyldiethylthiocarbamide hydriodide*, $C_6H_{14}N_2S,HI$, prepared by treating diethylcarbamide with methyl iodide, is a crystalline compound, very readily soluble in all ordinary solvents. The free *base* is a yellow, disagreeably-smelling oil, with a strong alkaline reaction. The *picrate*, $C_6H_{14}N_2S,C_6H_3N_3O_7$, separates from water in crystals melting at 116°. The *platinochloride*, $(C_6H_{14}N_2S)_2,H_2PtCl_6$, crystallises in plates.

Diethylguanidine is obtained when methyldiethylcarbamide is heated at 100° with alcoholic ammonia. It is a yellow oil, soluble in alcohol and ether; the *picrate*, $C_5H_{13}N_3,C_6H_3N_3O_7$, crystallises from water in long needles melting at 141°.

Triethylthiocarbamide hydriodide is deliquescent, and soluble in alcohol and ether. The *picrate*, $C_7H_{16}N_2S,C_6H_3N_3O_7$, crystallises in rhombohedra, and melts at 72°. The *platinochloride*,

$$(C_7H_{16}N_2S)_2,H_2PtCl_6,$$

is crystalline.

The picrate of *diethylpropylthiocarbamide* crystallises in plates, and melts at 65—66°.

Compounds analogous to those described above are obtained by treating diethylthiocarbamide with amyl iodide, allyl iodide, and benzyl chloride; *diethylamylthiocarbamide* and *diethylallylthiocarbamide* are colourless oils; *diethylbenzylthiocarbamide hydrochloride*, $C_{12}H_{18}N_2S,HCl$, crystallises in needles, and melts at 73—75°.

Diethylethylenepseudothiocarbamide,  $\begin{matrix}CH_2-S\\ |\\ CH_2\cdot NEt\end{matrix}\!\!>C{:}NEt$, is formed when diethylthiocarbamide is boiled with ethylene bromide for five to six hours, and the product decomposed with soda. It is a yellowish oil, boils at 224° (748 mm.), is volatile with steam, and is readily soluble in alcohol and ether, but only sparingly in water; its constitution is proved by the fact that, on oxidation with chlorine in dilute hydrochloric acid solution and subsequent decomposition with strong hydrochloric acid, it yields ethylamine, carbonic anhydride and taurine.

The *salt* $NHEt\cdot C(NEt)\cdot S\cdot CH_2\cdot CH_2\cdot S\cdot C(NEt)\cdot NHEt,2HBr$ is obtained when diethylthiocarbamide is treated with ethylene bromide at a temperature below 100°. It separates from alcoholic ether in colourless needles, melts at 184°, and is readily soluble in water and hot alcohol, but insoluble in benzene and light petroleum; when heated with potash, it yields ethylene mercaptan.

Diethyltrimethylenepseudothiocarbamide, $C_8H_{16}N_2S$, prepared by boiling diethylthiocarbamide with trimethylene bromide, forms a crystalline platinochloride, $(C_8H_{16}N_2S)_2,H_2PtCl_6$, which melts at 119° with decomposition; when the diethyl base is warmed with trimethylene bromide at a temperature below 100°, the compound $C_{13}H_{18}N_4S_2$ is formed. F. S. K.

The Furfuran-group. Supposed Isomerides of Pyromucic Acid and of Furfuraldehyde. By V. OLIVERI and A. PERATONER (*Gazzetta*, 19, 633—639; compare Maquenne, this vol., p. 33).—The authors find that Limpricht's isopyromucic acid (Abstr., 1873, 621), when thoroughly purified by crystallisation from benzene or toluene, is identical with ordinary pyromucic acid, since it melts at 128—131°, and yields an ethyl salt melting at 34—35° and boiling at 191°, and an amide melting at 141—142°. The β-pyromucic aldehyde (fucusaldehyde) obtained by Stenhouse dissolves in solutions of sodium hydrogen sulphite, but a small quantity of an oily, non-aldehydic substance may be extracted from the solution with ether. On adding a dilute solution of soda to the hydrogen sulphite and extracting with ether, a substance is obtained having the composition $C_5H_4O_2$, which distils between 158—160°, and has all the physical properties of furfuraldehyde. The hydrazones of these substances both crystallise in greyish laminæ melting at 90—92°. Fucusaldehyde was further converted into Stenhouse's β-pyromucic acid, which, after recrystallisation from toluene and benzene, has the same melting point as ordinary pyromucic acid (128—129°), and yields an identical ethyl salt and an amide.

It thus appears that fucusaldehyde is identical with furfuraldehyde, and that Limpricht's iso-acid and Stenhouse's β-acid are identical with ordinary pyromucic acid. S. B. A. A.

Conversion of Pyrroline into Tetramethylenediamine. By G. CIAMICIAN (*Gazzetta*, 19, 578—580).—Ciamician and Dennstedt (*ibid.*, 14, 156) observed that pyrroline unites with hydroxylamine, forming a solid compound, $C_4H_8N_2O_2$, which melts at 173°, and which they regarded as the dioxime of succinaldehyde, NOH:CH·CH_2·CH_2·CH:NOH. By treating this compound with sodium and absolute alcohol, a base is formed which is shown to be identical with tetramethylenediamine (putrescine) by its boiling point, 158—159°, the melting point of the benzoyl-derivative, 178°, and by the agreement of the crystalline form of the platinochloride and picrate with the corresponding tetramethylenediamine-derivatives. The hydrochloride of the base may be converted into pyrrolidine, and the aurochloride of the product is identical with that described by Ciamician and Magnaghi, melting with decomposition at 205—206°. The formation of tetramethylenediamine from pyrrolinehydroxylamine indicates the presence in the latter compound of the chain N·C·C·C·C·N; it is further probable that one molecule of pyrroline reacts with 2 molecules of hydroxylamine, the compound $(CH:CH·NH·OH)_2$ being first formed with elimination of ammonia, and subsequently converted into the more stable form $(CH_2·CH:NOH)_2$. Pyrrolinehydroxylamine somewhat resembles the glyoximes; it dissolves in alkalis, reacts with acetic anhydride, and evolves nitrous oxide when heated with nitrous acid. With phenylhydrazine, a dihydrazone, $(CH_2·CH:N_2HPh)_2$, is formed, which melts at 124—125°. S. B. A. A.

Action of Ethyl Oxalate on Pyrryl Methyl Ketone. By A. Angeli (*Ber.*, 23, 2154—2160; compare this vol., p. 1000).—An *azine* of the composition $C_{14}H_9N_3O$ is precipitated in dark-red crystals when pyrroylpyruvic anhydride (*loc. cit.*) is treated with orthophenylenediamine in alcoholic or acetic acid solution. It separates from boiling xylene as a reddish-yellow, crystalline powder, decomposes at about 250°, but without melting, and is only sparingly soluble in alcohol, ethyl acetate, and chloroform, but more readily in boiling xylene, the solutions showing a green fluorescence. It dissolves in concentrated sulphuric acid, forming an intense greenish-blue solution, from which it is reprecipitated on the addition of water. On reduction with zinc and acetic acid, it yields a yellow solution which turns red again on exposure to the air. The *benzoyl*-derivative crystallises in yellow needles, melts at 166° with decomposition, and is soluble in benzene and chloroform, the solutions showing a green fluorescence.

Ethyl anilpyrroylpyruvate, $C_{16}H_{16}N_2O_3$, is formed when ethyl pyrroylpyruvate is warmed with aniline in acetic acid solution. It crystallises from alcohol in long, lemon-yellow needles, melts at 114—115°, and dissolves in concentrated sulphuric acid with a magenta coloration.

Anilpyrroylpyruvic anhydride, $C_{14}H_{10}N_2O_2$, is deposited in yellowish-orange plates when the preceding compound is treated with warm alcoholic ammonia; it can also be prepared by warming pyrroylpyruvic anhydride with aniline in acetic acid solution. It melts at 218°, dissolves in concentrated sulphuric acid with a violet coloration, and does not combine with orthophenylenediamine.

Anilpyrroylpyruvic acid, $C_{14}H_{12}N_2O_3$, is precipitated in crystals when the ethyl salt is treated with cold dilute alcoholic potash, and the aqueous solution of the product acidified. It separates from benzene in orange crystals, melts at 179° with decomposition, and dissolves in concentrated sulphuric acid with a magenta coloration. Most metallic salts produce a yellow precipitate in an aqueous solution of the ammonium salt.

A compound of the composition $C_{12}H_{11}NO_3$ is obtained when ethyl benzoylpyruvate is heated with hydroxylamine hydrochloride in alcoholic solution; it crystallises from alcohol in large, colourless prisms, melts at 52°, and has the constitution  $\begin{array}{l}\mathrm{CPh{\cdot}CH} \\ \| \\ \mathrm{N{-\!\!-}O}\end{array}\!\!>\!\mathrm{C{\cdot}COOEt}$ or  $\begin{array}{l}\mathrm{CPh{:}CH} \\ | \\ \mathrm{O{-\!\!-}N}\end{array}\!\!>\!\mathrm{C{\cdot}COOEt}$. The compound formed by the action of hydroxylamine on ethyl pyrroylpyruvate (*loc. cit.*) has probably an analogous constitution. The *acid* prepared from this ethyl salt (m. p. 52°) melts at 162°.

Ethyl pyrrylphenylpyrazolecarboxylate, $C_{16}H_{15}N_3O_2$, prepared by warming ethyl pyrroylpyruvate with phenylhydrazine in glacial acetic acid solution, separates from alcohol in small crystals melting at 168°. The free *acid*, $C_{14}H_{11}N_3O_2$, crystallises from dilute alcohol in long, colourless needles, melts at 215°, and decomposes at a higher temperature. It is readily soluble in alcohol and acetone, but almost insoluble in benzene and light petroleum. In an aqueous solution of the ammonium salt, many metallic salts produce precipitates.

F. S. K.

The Pyrazole-group: Derivatives of Trimethylenephenyldiamine. By L. Balbiano (*Gazzetta*, **19**, 688—692).—*Trimethylenephenyldiamine*, $NH_2{\cdot}C_3H_6{\cdot}NHPh$.—A solution of 1-phenylpyrazole in absolute alcohol (20 parts) is reduced with metallic sodium, the product distilled and freed from alcohol, and the base extracted with ether and converted into the oxalate. The yield is 45 per cent. The base (obtained from the oxalate) boils constantly at 281—282° (corr.) under a pressure of 758·1 mm.; sp. gr. 0°/0° = 1·0356; 15°/0° = 1·0256. It is soluble in ether and alcohol, but only very moderately in water. A solution in excess of hydrochloric acid is not precipitated by the double iodide of potassium and bismuth. The *succinate* crystallises from alcohol in tufts of large, white, lustrous plates, melts at 100—102° (corr.), and dissolves very readily in cold water, but is insoluble in ether.

Dibenzoyltrimethylenephenyldiamine, $NHBz{\cdot}C_3H_6{\cdot}NPhBz$. — Trimethylenephenyldiamine is quantitatively converted into the benzoyl-derivative by treatment with benzoic chloride and sodium hydroxide in the cold. It thus behaves like the diamines, which have the NH_2 molecules linked to different carbon-atoms (see Udránszky, Abstr., 1888, 1296). It crystallises in pinkish-white plates, melts at 96·5—97·5°, and is soluble in water, but not in alcohol. *Trimethylenephenyldiamine trimethylenephenylthiocarbamate*,

$$NHPh{\cdot}C_3H_6{\cdot}NH{\cdot}CSSH,NH_2{\cdot}C_3H_6{\cdot}NHPh,$$

is prepared by adding a slight excess of carbon bisulphide to a solution of the base in dilute alcohol and agitating the mixture. A waxy mass separates at first, but is redissolved after boiling for some time. The filtered solution, on cooling, deposits white plates of the new compound which decompose at 116° and are only sparingly soluble in water. With mercuric chloride, the hot aqueous solution yields a white precipitate which is converted into mercuric sulphide by prolonged boiling. The dry mercuric compound decomposes at 210—220°, giving off white fumes which condense to a yellowish liquid having an odour of oil of mustard. S. B. A. A.

Derivatives of Furoïn and Furil. By D. S. Macnair (*Annalen*, **258**, 220—230).—*Furoinphenylhydrazine*,

$$C_4H_3O{\cdot}CH(OH){\cdot}C(N_2HPh){\cdot}C_4H_3O,$$

prepared by treating furoïn with phenylhydrazine and a few drops of acetic acid in alcoholic solution, crystallises from a mixture of benzene and light petroleum in colourless needles, melts at 79—81°, and is very readily soluble in alcohol, ether, and benzene, but almost insoluble in water and light petroleum; it rapidly oxidises on exposure to the air, and is readily acted on by hydrochloric acid. The *oxime*, $C_{10}H_9NO_4$, crystallises from alcohol in small, almost colourless prisms, melts at 160—161°, and is readily soluble in hot, but only sparingly in cold, alcohol and benzene; it dissolves freely in soda, yielding a crystalline sodium-derivative.

Deoxyfuroïn, $C_4H_3O{\cdot}CO{\cdot}CH_2{\cdot}C_4H_3O$, can be obtained by treating furoïn with zinc-dust and hydrochloric acid in alcoholic solution, and distilling the product with steam; it melts at 20°, boils at 159—160° (27 mm.), and is only sparingly soluble in water, but readily in ether and alcohol. The *oxime*, $C_{10}H_9NO_3$, crystallises in colourless needles, melts at 94—96°, and is readily soluble in alcohol, ether, benzene, hydrochloric acid, and soda, but only sparingly in water or light petroleum.

Furilphenylhydrazone, $C_4H_3O{\cdot}CO{\cdot}C(N_2HPh){\cdot}C_4H_3O$, crystallises from boiling light petroleum in orange-yellow needles, melts at 82—83°, and is readily soluble in alcohol, ether, and benzene, but only sparingly in light petroleum and boiling concentrated hydrochloric acid.

Furilphenylosazone, $C_4H_3O{\cdot}C(N_2HPh){\cdot}C(N_2HPh){\cdot}C_4H_3O$, prepared by treating furil with phenylhydrazine (2 mols.) in alcoholic acetic acid solution, crystallises from alcohol in yellowish needles, melts at 184°, and is very sparingly soluble in alcohol and light petroleum, but more readily in ether and benzene; it is only very slowly acted on by hot hydrochloric acid.

α-Furiloxime, $C_{10}H_7NO_4$, is formed, together with small quantities of the β-oxime, when furil is treated with hydroxylamine hydrochloride in alcoholic solution at the ordinary temperature. It crystallises from a mixture of benzene and light petroleum in colourless needles, melts at 160°, decomposes at about 200°, and is only sparingly soluble in water and light petroleum, but very readily in most other solvents. When warmed with dilute hydrochloric acid, it is changed into furil. The *β-oxime*, $C_{10}H_7NO_4$, is formed when furil is heated at 100° with an alcoholic solution of hydroxylamine hydrochloride (1 mol.), but a considerable quantity of furil remains unchanged. It separates from water in crystals, melts at 97—98°, and is readily soluble in alcohol, ether, and benzene, but only sparingly in water and light petroleum: it dissolves in soda, and is decomposed by boiling hydrochloric acid. The *α-dioxime*, $C_{10}H_8N_2O_4$, prepared by treating furil with excess of hydroxylamine hydrochloride as described in the case of the α-oxime, crystallises from hot water in colourless needles containing 1 mol. H_2O, and loses its water of crystallisation at 100°, the anhydrous substance melting at 166—168°. It is very readily soluble in alcohol and ether, but only sparingly in benzene, light petroleum, and water; it dissolves freely in soda, and is decomposed by boiling hydrochloric acid. The *β-dioxime*, $C_{10}H_8N_2O_4$, is obtained when the anhydrous α-dioxime is heated with alcohol at 150—160°; it separates from a mixture of ether and light petroleum in crystals, melts at 188—190° with partial decomposition, and is only moderately easily soluble in ether. F. S. K.

Synthesis of Tetraphenylthiophen. By J. H. Ziegler (*Ber.*, **23**, 2472—2476).—The author has previously prepared tetraphenylethylene by the action of sulphur on diphenylmethane (compare Abstr., 1888, 596). Further experiments with benzene-derivatives containing a CH_3- or CH_2-group have shown that the benzene nucleus only reacts with great difficulty, and in exceptional circumstances. *Tetraphenylthiophen* is prepared by heating phenylacetic acid (2 mols.) with sulphur (1 mol.) for six hours at 260°; the product is dissolved in benzene, and, on the addition of alcohol, it crystallises in white needles melting at 181—182°. The same compound is also obtained from deoxybenzoïn by heating with sulphur as above. By the action of concentrated nitric acid on tetraphenylthiophen, a *tetranitro-derivative* is formed. Benzophenone, azobenzene, and triphenylmethane do not react with sulphur at 300°. The author points out that in cases where sulphur combines with the benzene nucleus there is always a basic group present, and this he regards as the reason for the combination taking place; the difference in behaviour of diphenylmethane and triphenylmethane towards sulphur tells, he considers, strongly in favour of his view. The author confirms the conclusions of Pfitzinger and Gattermann regarding the constitution of dehydrothiotoluidine. J. B. T.

Orientation of 4 : 6-Dichlorometaxylene, and on some Derivatives thereof. By A. Claus and G. Runschke (*J. pr. Chem.* [2], **42**, 110—126).—The authors have decided the orientation of the chlorine-atoms in the dichlorometaxylene (m. p. 68°) described by Claus and Burstert (this vol., p. 1105). They did not succeed in obtaining a durene from it by Fittig's reaction, but a dinitro-derivative (see below) can be obtained, which, by conversion into the amido-derivative and oxidation, is converted into a dichlorometaxyloquinone, whose properties show it to be a para-compound; this is conclusive evidence that the dinitro-derivative is a para-compound, and as 2 and 5 are the only possible para-positions in a metaxylene [1 : 3], the chlorine-atoms must have the positions 4 : 6. It is hoped that a general method of orientation may be deduced from the above considerations.

Nitro-4 : 6-dichlorometaxylene, obtained by nitrating 4 : 6-dichlorometaxylene with fuming nitric acid in glacial acetic acid at the ordinary temperature, and repeatedly crystallising from alcohol, forms transparent crystals, measurements of which are given; it melts at 118—119°, and is insoluble in the usual solvents. An isomeric nitro-compound has been obtained under somewhat different conditions; it melts at 106° (uncorr.).

Amido-4 : 6-dichlorometaxylene is obtained by pouring an alcoholic solution of the nitro-compound little by little into a solution of stannous chloride in strong hydrochloric acid and warming for 3—4 hours on the water-bath; the *stannochloride* crystallises on cooling and may be decomposed by aqueous potash. It forms colourless needles, which soon become coloured, melts at 85° (uncorr.), and dissolves in the usual solvents. Its *hydrochloride* and *platinochloride* have been obtained. The amido-derivative corresponding with the nitro-derivative melting at 106° melts at 72° (uncorr.).

2 : 5-*Dinitro-4 : 6-dichlorometaxylene* is prepared by adding the dichloroxylene (1 part) in small quantities to a mixture (5 parts) of 1 part of fuming nitric acid (sp. gr. 1·52) and 2 parts of sulphuric acid, and pouring the mixture into water after a day; it separates in yellow flocks, which are washed with hot alcohol to dissolve the nitro-derivative. It crystallises from chloroform in pale-yellow cubes, melts at 223° (uncorr.), and dissolves freely in chloroform and glacial acetic acid. When it is suspended in alcohol and acted on with stannous chloride, it yields 2 : 5-diamido-4 : 6-dichlorometaxylene. This crystallises in dazzlingly white prisms or needles when pure, but the crystals are generally yellowish or rosy; it melts at 176° (uncorr.); the *hydrochloride*, *sulphate*, and *platinochloride* are described.

Dichlorometaxyloquinone is obtained by oxidising the diamido-compound in dilute glacial acetic acid solution with dilute aqueous chromic acid; it crystallises in large, pretty, sulphur-yellow leaves which melt at 178° (uncorr.), sublime, and dissolve in the usual solvents. By reduction with stannous chloride it yields *dichlorometaxyloquinol* (dichlorodimethylquinol) [$Me_2 : Cl_2 : (OH)_2 = 1 : 3 : 4 : 6 : 2 : 5$], which crystallises in slender, colourless needles melting at 224° (uncorr.), and soluble in the usual solvents.

2 : 5-*Dibromo-4 : 6-dichlorometaxylene* is formed when 4 : 6-dichlorometaxylene is treated with bromine (4 atoms) and iron in glacial acetic acid for some days and water added. It crystallises from ether, benzene, &c., in long, brilliant, white, silky needles which melt at 230° (uncorr.), and can be sublimed. If only 2 atoms of bromine are employed, the same dibromo-compound is formed and half the dichloro-compound remains unchanged. A. G. B.

Dibromoxylenes and Dichloroxylenes, and their Transformations by means of Sulphuric Acid. By E. Koch (*Ber.*, 23, 2318—2321).—Solid dibromoxylene [$Me_2 : Br_2 = 1 : 4 : 2 : 5$], when heated with concentrated sulphuric acid at 215°, yields a liquid isomeride boiling at 260—265°, probably [1 : 4 : 2 : 3]. Under similar circumstances the solid 1 : 2 : 4 : 5-compound yields the isomeric 1 : 2 : 3 : 4-compound, boiling at 275—280°.

By the action of chlorine and iodine on cold metaxylene, two dichlorinated derivatives are obtained. One is a solid, melting at 68·5° and boiling at 223—224°. When treated with methyl iodide and sodium, it yields durene, and has therefore the formula [Me$_2$: Cl$_2$ = 1 : 3 : 4 : 6]. By treatment with chlorosulphonic acid it yields a sulphonic acid of the formula [Me$_2$: Cl$_2$: SO$_3$H = 1 : 3 : 4 : 6 : 2]. The sodium salt forms white plates, the potassium salt white needles, and both are soluble in water; the calcium and barium salts form brilliant, white plates, only sparingly soluble in water. The amide forms small plates melting with decomposition above 250°. The other dichlorometaxylene is a liquid solidifying at −20° and boiling at 221·5°. It is convertible into prehnitene and has therefore the formula [Me$_2$: Cl$_2$ = 1 : 3 : 2 : 4]. The sulphonic acid has the formula [Me$_2$: Cl$_2$: SO$_3$H = 1 : 3 : 2 : 4 : 6]. The potassium and sodium salts form brilliant needles very soluble in water, the calcium and barium salts very sparingly soluble, shining plates. The amide forms small, white plates melting with decomposition above 300°. The constitution of the sulphonic acids was determined by means of the metaxylenesulphonamides which they yield when treated with zinc-dust and ammonia. When the solid dichloroxylene is heated with strong sulphuric acid at 220°, about 12 per cent. is changed into the liquid isomeride.

Dibromodichloroxylene [Me$_2$: Cl$_2$: Br$_2$ = 1 : 3 : 2 : 4 : 5 : 6], obtained by the action of bromine on cold dichloroxylene, crystallises from acetic acid in brilliant, silky needles melting at 215°, and scarcely soluble in alcohol.

Dinitrodichloroxylene [Me$_2$: Cl$_2$: (NO$_2$)$_2$ = 1 : 3 : 2 : 4 : 5 : 6], obtained by adding dichloroxylene to a warm mixture of nitric and sulphuric acids, crystallises from alcohol in brilliant, pale-yellow needles melting at 155°.

Dinitrodichloroxylene [1 : 3 : 4 : 6 : 2 : 5], obtained as above from the corresponding dichloroxylene, crystallises from acetic acid and alcohol in short, hard prisms melting at 215°.

Tetrachlorometaxylene, formed together with symmetrical dichlorometaxylene when metaxylene is chlorinated, crystallises from acetic acid in flexible needles melting at 212°.

A solid *dichlororthoxylene* is formed in small quantity in addition to a liquid isomeride when orthoxylene is chlorinated. It crystallises from alcohol in long, hard needles melting at 73°. C. F. B.

Laurenes. By E. Uhlhorn (*Ber.*, **23**, 2346—2349).—On distilling camphor with zinc chloride, a considerable quantity of liquid is obtained, boiling at 180—200°, which is known to be a mixture of various hydrocarbons. From the fraction boiling at 183—184·5°, derivatives of ethylxylene [Me : Me : Et = 1 : 2 : 4] are obtained. The portion boiling at 188—190° yields derivatives of ethylxylene [Me : Me : Et = 1 : 4 : 5]. The intermediate fraction boiling at 185—187° in all probability consists of ethylxylene [Me : Me : Et = 1 : 3 : 4]. From the portions boiling at 190—192°, a mixture of the barium sulphonates of the first two ethylxylenes is obtained, together with a resinous, amorphous salt. The various compounds serving for identification were in all cases compared with synthetical specimens. These results are in accordance with the observations of Armstrong and Miller (compare Abstr., 1884, 43). J. B. T.

Propylxylenes. By E. UHLORN (*Ber.*, **23**, 2349—2351).—Propylorthoxylene [Me : Me : Pr^{a} = 1 : 2 : 4] is prepared from bromorthoxylene and propyl bromide; it boils at 209° and does not solidify at —20. The *sulphonic acid* crystallises in slender needles. The *barium sulphonate*, $(C_{11}H_{15}SO_3)_2Ba + 3\frac{1}{2}H_2O$, forms nodular crystals. The *magnesium* salt, $(C_{11}H_{15}SO_3)_2Mg + 5H_2O$, crystallises in plates. The *sodium sulphonate*, $C_{11}H_{15}SO_3Na + H_2O$, is deposited in lustrous prisms. *Propylorthoxylenesulphonamide* crystallises in needles melting at 123—124°. The *sulphanilide* forms interlaced needles and melts at 213—214°. *Tribromopropylorthoxylene* is obtained in long, white needles melting at 48°.

Propylmetaxylene [Me : Me : Pr^{a} = 1 : 3 : 4] boils at 208—208·5° and remains liquid at —20. The *sulphonic acid* crystallises in groups of needles. The *barium salt*, $(C_{11}H_{15}SO_3)_2Ba + 2H_2O$, forms needles; the *magnesium salt*, $(C_{11}H_{15}SO_3)_2Mg + 5H_2O$, is deposited in thin, colourless plates; the *sodium salt*, $C_{11}H_{15}SO_3Na + 4\frac{1}{2}H_2O$, crystallises in long, transparent needles. *Propylmetaxylenesulphonamide* is obtained in needles melting at 102°. The *sulphanilide* melts at 180—182°. The *trinitro-* and *tribromo*-derivatives crystallise in needles, and melt at 110° and 39° respectively.

Propylparaxylene [Me : Me : Pr^{a} = 1 : 4 : 5] boils at 206—207°, and does not solidify at —20°. The *sulphonic acid* crystallises in needles. The *barium salt* forms anhydrous, lustrous tables. The *sodium salt*, $C_{11}H_{15}SO_3Na + 1\frac{1}{2}H_2O$, is readily soluble in water, and is deposited in lustrous needles. *Propylparaxylenesulphonamide* crystallises in thin plates melting at 124·5°. The *sulphanilide* is obtained in rhombic crystals melting at 215—216°. The *trinitro-derivative* melts at 85°, and the *tribromo-compound* at 49°; both crystallise in needles.

Isopropylmetaxylene [Me : Me : Pr^{β} = 1 : 3 : 4] is prepared by treating paraisocymene with bromine and methyl bromide successively; it boils at 194—195°. The *sulphonic acid* crystallises in prisms. The *barium sulphonate* is readily soluble in water, and is deposited in spear-shaped needles. The *sodium sulphonate*, $C_{11}H_{15}SO_3Na + 4H_2O$, forms long, slender needles. The *sulphonamide* melts at 163°; the *sulphanilide* at 207°; the *tribrominated* derivative at 261°; and the *trinitro*-derivative at 182°; all four compounds crystallise in needles.

J. B. T.

Orthocyanobenzyl Chloride. By A. W. DAY and S. GABRIEL (*Ber.*, **23**, 2478—2489).—It is well known that ortho-derivatives of benzonitrile, containing a hydroxyl-group in the side chain, readily undergo rearrangement, with formation of the group ·C:NH·O·. The same property is shown by the corresponding mercaptan-derivatives. *Orthocyanobenzyl thiocyanate*, $CN·C_6H_4·CH_2·SCN$, is prepared by boiling orthocyanobenzyl chloride with an alcoholic solution of potassium thiocyanate for about two hours; on pouring the solution into water an oil separates, which solidifies, and, after some time, is purified by washing with water and dilute alcohol; 15·5 grams of cyanobenzyl chloride yield 16—17 grams of the thiocyanate. The compound crystallises from dilute alcohol in colourless needles melting at 86°. By the action of concentrated hydrochloric acid on the thiocyanate at 180°, thiophthalide is obtained; it has previously been prepared by Graebe (compare Abstr., 1889, 140) by the action of an alkaline hydrogen sulphide on nitrosophthalimidine, and has the second of the proposed formulæ, namely, $C_6H_4<\substack{CO\\CH_2}>S$ (see below). Cyanobenzyl thiocyanate is dissolved in concentrated sulphuric acid, and the solution heated, first at 30—50°, and finally at 60—70°; on pouring into water and adding ammonia, an oily liquid separates and solidifies on cooling. It is soluble in alcohol and ether, and crystallises from light petroleum in small, white needles melting at 62°, and becoming brown on exposure to air. This compound affords a striking instance of tautomerism; it reacts both as *orthocyanobenzyl mercaptan*, $CN\cdot C_6H_4\cdot CH_2\cdot SH$, and as *thiophthalimidine*, $C_6H_4<\substack{C:NH\\CH_2-}>S$. The same substance is also obtained by the action of the calculated quantity of alcoholic potassium hydrosulphide on orthocyanobenzyl chloride: after remaining for an hour the liquid is treated with hydrochloric acid, the alcohol removed, and the compound precipitated with ammonia from an aqueous solution (see below). By the action of sodium hydroxide on this compound, ammonia is eliminated, and thiomethylbenzoic acid is formed, which yields thiophthalide on boiling with water.

DERIVATIVES OF THIOPHTHALIMIDINE.—In the following reactions the compound C_8H_7NS behaves as if it were thiophthalimidine. The *platinochloride*, $(C_8H_7NS)_2,H_2PtCl_6$, crystallises in orange-yellow prisms. The *picrate* is deposited in slender needles. The *hydrochloride* dissolves very readily in water, and is partly decomposed on evaporating the solution; it crystallises in white needles. The *hydriodide* is obtained in colourless needles, which decompose at 100°. *Methylthiophthalimidine*, $C_6H_4<\substack{C(NMe)\\CH_2-S}>$, is prepared by dissolving thiophthalimidine in excess of methyl iodide: after remaining for 1—2 hours the crystals of thiophthalimidine hydriodide are separated, and the residue distilled in a current of steam; on extracting the distillate with ether, and evaporating the latter, a yellow, basic oil remains, which decomposes on heating. The yield is one-third of the theoretical. The *hydrochloride*, $C_8H_6Me\cdot NS,HCl$, is stable at 100°; the *platinochloride* forms a sparingly soluble, brownish-yellow, crystalline powder; the *picrate* crystallises in yellow needles. The constitution of the base is shown by the formation of thiophthalide and methylamine on heating it with concentrated hydrochloric acid at 180—190° for five hours.

In the following reactions the compound C_8H_7NS behaves like *orthocyanobenzyl mercaptan*. *Methyl orthocyanobenzyl sulphide*, $CN\cdot C_6H_4\cdot CH_2\cdot SMe$, is formed by the action of methyl iodide on an alkaline solution of the mercaptan; it is a pale-yellow, viscid liquid, boiling at 278° under a pressure of 757 mm., and does not show basic properties; by the action of concentrated hydrochloric acid at 100°, ammonia is eliminated, and *methylbenzylsulphide-orthocarboxylic acid*, $COOH \cdot C_6H_4 \cdot CH_2 \cdot SMe$, is formed. *Diorthocyanobenzyl disulphide*, $CN \cdot C_6H_4 \cdot CH_2 \cdot S_2 \cdot CH_2 \cdot C_6H_4 \cdot CN$, is prepared by the action of potassium ferrocyanide on an alkaline solution of the mercaptan. It crystallises from alcohol in long prisms which melt at 124°. On heating it with concentrated hydrochloric acid at 160°, ammonia, sulphuric acid, and thiophthalide are formed; it is probable, however, that in the first instance, a dicarboxylic acid, $COOH \cdot C_6H_4 \cdot CH_2 \cdot S_2 \cdot CH_2 \cdot C_6H_4 \cdot COOH$, is produced, and that this decomposes into thiophthalide, water, and oxygen.

In addition to the compound C_8H_7NS (see above), a substance of the formula $C_{16}H_{10}S_3$ is formed by the action of excess of alcoholic potassium hydrosulphide (3—4 mol. proportions) on orthocyanobenzyl chloride (comp. this vol., p. 1221). The compound is deposited in small, flat needles, which appear brown by transmitted light, and have a metallic dark-green tint in reflected light; it is very sparingly soluble in ordinary media, but may be recrystallised from nitrobenzene. With concentrated sulphuric acid, a magenta colour is obtained, and on adding water the compound is precipitated seemingly unchanged. The same substance is formed by the action of alcoholic potassium hydrosulphide on thiophthalimidine.

Diorthocyanodibenzylamine, $(CN \cdot C_6H_4 \cdot CH_2)_2NH$, is prepared by dissolving orthocyanobenzyl chloride in a 10 per cent. alcoholic solution of ammonia; after remaining for about six days at the ordinary temperature, the crystals which form are separated, washed with alcohol, and decomposed with sodium hydroxide. It crystallises from water in slender needles, melts at 125°, and is readily soluble in alcohol. The *hydrochloride* is deposited in needles; the *platinochloride* forms a yellowish-red, crystalline powder. On evaporating the ammoniacal mother liquors obtained in the preparation of the above base, crystals of orthocyanobenzylamine hydrochloride are deposited; this compound has already been described. J. B. T.

Benzoyl-derivatives of Acetonitrile. By E. v. MEYER (*J. pr. Chem.* [2], **42**, 267—269).—Monobenzoylacetonitrile or cyanacetophenone is obtained from imidobenzoylcyanomethyl (Abstr., 1888, 683) by shaking it with hydrochloric acid. The precipitate, on solution in ethyl acetate and addition of light petroleum, forms snow-white needles melting at 80·5—81°, and agrees in all its properties with the cyanacetophenone described by Haller (Abstr., 1889, 473).

If a mixture of acetonitrile and benzoic chloride be treated with sodium in ethereal solution, *dibenzoylacetonitrile*, $CBz_2H \cdot CN$, is formed, together with methane, sodium cyanide, and other organic sodium salts. The precipitate, after washing with ether, is dissolved in water, the solution extracted with ether, and acidified with sulphuric acid. The voluminous precipitate is then recrystallised from alcohol, and forms silky needles melting at 156·5°. It readily yields a silver salt. Towards alkalis it is exceptionally stable, but it is decomposed on warming with moderately dilute sulphuric acid, with formation of carbonic anhydride, acetophenone, benzoic acid, and ammonia. On warming the silver salt with methyl iodide, a compound was obtained, crystallising from ethyl acetate in lustrous needles which melted at 214°, and were insoluble in dilute ammonia. The quantity was, however, too small to determine whether it was the *methyl* ether, $CBz_2Me·CN$.

Further investigation is also necessary to determine whether dibenzoylacetonitrile has the constitution assigned to it above, as its properties agree equally well with the formula $OH·PhC:CBz·CN$.

H. G. C.

Tricyanides. By F. Krafft and G. Koenig (*Ber.*, 23, 2382—2388; compare Abstr., 1889, 696).—Methyl diphenyl tricyanide is best prepared by pouring the product obtained from the action of aluminium chloride on benzonitrile and acetic chloride into ice-cold water, and distilling the insoluble portion in a current of steam; the residue is finely ground, treated with dilute sodium hydroxide solution, washed with water, and recrystallised from alcohol.

Diphenyltricyanocarboxylic acid, $C_3N_3Ph_2·COOH$, is obtained by boiling methyldiphenyl tricyanide for 12 to 15 hours with potassium permanganate in alkaline solution; the product is filtered hot, the manganese precipitate boiled with water, and the solution, when nearly cold, treated with hydrochloric acid. The acid, which separates as a voluminous precipitate, crystallises from dilute alcohol in slender, thin, lustrous prisms melting at 192° with decomposition. The *potassium salt* crystallises in long, slender, lustrous needles, very sparingly soluble in water. *Hydrogen diphenyl tricyanide*, $C_3N_3HPh_2$, is obtained by heating the carboxylic acid at about 192°; it melts at 75°, boils at 205° at 9 mm., and is readily soluble in dilute alcohol.

Caprylic chloride, $C_7H_{15}·COCl$, is prepared by the action of phosphorus pentachloride on caprylic acid at 0°; it boils at 83° at 15 mm. *Heptyl diphenyl tricyanide*, $C_3N_3(C_7H_5)Ph_2$, is obtained by the action of aluminium chloride on benzonitrile and caprylic chloride; it crystallises from alcohol in lustrous leaves melting at 28°, and boiling at 274—275° under a pressure of 15 mm.

Nonylic chloride, $C_7H_{17}·COCl$, is formed from nonylic acid and phosphorus pentachloride; it is a colourless liquid, boiling at 98° under a pressure of 15 mm.; on exposure to moist air it slowly undergoes decomposition. *Octyl diphenyl tricyanide*, $C_3N_3(C_8H_{17})Ph_2$, is prepared from nonylic chloride; it is purified by recrystallisation from alcohol, melts at 43°, and boils at 284—285° under a pressure of 15 mm.

Capric chloride, $C_9H_{19}·COCl$, is obtained from capric acid; it boils at 114° under a pressure of 15 mm., and rapidly decomposes on exposure to air. *Nonyl diphenyl tricyanide*, $C_3N_3(C_9H_{19})Ph_2$, is formed from capric chloride; it may be crystallised from alcohol; it melts at about 38°, and boils at 292—294° under a pressure of 15 mm. A comparison of the melting points of this series of tricyanides with those of the normal fatty acids shows the same regularity. The melting points of tricyanides obtained from acids with an even number of carbon-atoms follow a curve, and, in the case of the whole series, they rise and fall periodically from member to member. In contrast to this, the boiling points steadily rise with increasing molecular weight.

Methyl diparatoluyl tricyanide, $C_3N_3Me(C_6H_4Me)_2$, is prepared from paratoluonitrile and acetic chloride; it is very sparingly soluble in alcohol, but crystallises from isobutyl alcohol in small, lustrous needles melting at 159°, and boiling at 245° under a pressure of 15 mm.; the yield is large.

The chlorides of the bibasic acids condense to form tricyanide-derivatives in a similar manner to those of the monobasic acids. *Ethylene tetraphenyl hexacyanide*, $C_3N_3Ph_2{\cdot}CH_2{\cdot}CH_2{\cdot}C_3N_3Ph_2$, is obtained from benzonitrile and succinic chloride by heating with aluminium chloride on the water-bath for several days; the product is washed with ice-cold water, and extracted several times with ether; after evaporation, the residue is dissolved in nitrobenzene, and, on cooling, it crystallises in slender, lustrous plates which melt about 245°.

J. B. T.

Action of Benzoic Chloride on Sodium Cyanamide in the Presence of Ether. By W. Buddéus (*J. pr. Chem.* [2], **42**, 82—109).—Gerlich (this Journal, 1876, ii, 196) did not succeed in producing benzoylcyanamide by the action of benzoic chloride on sodium cyanamide in molecular proportion, and in ethereal solution. The author finds that sodium cyanamide (2 mols.) acts on benzoic chloride (1 mol.) in ether with the formation of sodium benzoylcyanamide, cyanamide, and sodium chloride.

Benzoylcyanamide, $NHBz{\cdot}CN$, is obtained from the sodium compound by the action of mineral acids; it melts at 126°, at the same time becoming yellow, and decomposing with the formation of benzonitrile, carbonic anhydride, and dicyanodiamide; it is not precipitated from its metallic compounds by organic acids, so that sodium acetate solution easily dissolves it; its solution in water is strongly acid, and its metallic compounds are neutral. Benzoylcyanamide is not polymerised by heat, either by itself or in liquids of high boiling point; when heated with an alcohol, it yields the corresponding benzoate and cyanamide. The metallic compounds of benzoylcyanamide are easily soluble in water and alcohol, except the silver compound. The *barium compound*, $Ba(NBz{\cdot}CN)_2,H_2O$, when heated, decomposes into benzonitrile, carbonic anhydride, and barium cyanamide; the *sodium*, *potassium*, *ammonium*, *copper* (with 2 mols. H_2O), *lead*, and *silver* compounds are also described.

The product of the action of sodium cyanamide on benzoic chloride in molecular proportion, dissolved in ether, after being washed, first with ether and then with water, leaves a yellow mass, which contains two isomeric compounds of the formula $(C_7H_4N_2)_x$. The other products formed by this treatment are carbonic anhydride, hydrogen cyanide, benzonitrile, cyanamide, sodium chloride, dibenzoylcyanamide, and asymmetrical dibenzoylcarbamide.

The *asymmetrical dibenzoylcarbamide*, $NBz_2{\cdot}CO{\cdot}NH_2$, is produced by the action of water on the dibenzoylcyanamide contained in the residue left on evaporating the yellow ethereal solution; it crystallises from alcohol in slender, white needles which melt at 197°, whereas symmetrical dibenzoylcarbamide melts at 210°.

The *compounds*, $(C_7H_4N_2)_x$, left in the yellow mass after treatment with water, are recrystallised from phenol, when one of them separates in the form of brilliant, long, yellow needles; the other crystallises from the mother liquor in short, well-formed, hexagonal and rhombic prisms. From about 800 grams of sodium cyanamide, 20 to 30 grams of the needles and 5 grams of the prisms were obtained. These compounds do not melt at 360°, but sublime unchanged at a red heat; they are unchanged even by prolonged heating with fuming nitric acid; they are insoluble in the usual solvents, but dissolve in liquids of high boiling point, such as phenol, aniline, nitrobenzene, quinoline, and benzonitrile.

Gerlich (*loc. cit.*) obtained a substance by the dry distillation of tribenzoylmelamine, which he termed pseudotriphenylmelamine, and to which he ascribed the formula $(C_7H_6N_2)_x$. The author believes that this substance is identical with those described above, and that Gerlich's formula is wrong. The investigation of these substances is being continued. A. G. B.

Orthamidobenzyl Alcohol. By H. G. Söderbaum (*Ber.*, 23, 2183—2187; compare Söderbaum and Widman, this vol., p. 178).—When phenomethyldihydroketometadiazine is oxidised with chromic acid in glacial acetic acid solution, it is converted into γ-methylbenzoylenecarbamide (m. p. 234°), identical with the compound prepared by Abt (Abstr., 1889, 609) from orthamidomethylbenzamide and carbamide. This same substance is also formed when phenomethyldihydroketothiometadiazine is oxidised with potassium permanganate.

Phenoethyldiketometadiazine (*γ-ethylbenzoylenecarbamide*),

$$C_6H_4<\begin{matrix}CO\cdot NEt\\ NH\cdot CO\end{matrix},$$

can be obtained by oxidising phenoethyldihydrothiometadiazine with potassium permanganate and decomposing the crystalline potassium salt produced in this way with acetic acid. It crystallises from boiling alcohol in colourless needles or plates, melts at 195°, and resembles the corresponding methyl-derivative in its behaviour with solvents; its solution in alcoholic potash shows a bluish-violet fluorescence. F. S. K.

Action of Chromyl Dichloride on Cymene. By G. Errera (*Gazzetta*, 19, 528—532; compare Abstr., 1880, 467; 1881, 423—581; 1884, 312).—When the product of the action of chromyl dichloride on cymene is decomposed with water, two isomeric compounds, having the formula $C_6H_4Me\cdot C_3H_5O$, are obtained; one of these combines with the hydrogen sulphites, and appears to be identical with Richter and Schüchner's paramethylhydrocinnamaldehyde (Abstr., 1884, 1342), but does not form crystals on prolonged exposure to the air; its aldehydic character is, however, shown by its conversion into an *alcohol*, $C_6H_4Me\cdot C_3H_6\cdot OH$, by the action of nascent hydrogen. This alcohol boils at 237—239°, and yields with hydrochloric acid the corresponding *chloride*, $C_6H_4Me\cdot C_3H_6Cl$, boiling at 225—230°; the latter, on being boiled with acetic acid and silver acetate, is converted into the *acetate*, $C_6H_4Me{\cdot}C_3H_6{\cdot}OAc$, which boils at 240—245°; by treatment with alcoholic potash, the unsaturated hydrocarbon, $C_6H_4Me{\cdot}C_3H_5$, boiling at 198—200, is formed. This hydrocarbon appears to be identical or isomeric with the α-paratolylpropylene previously described by the author (Abstr., 1885, 655).

The other isomeride boils at 222—226°, and does not combine with the hydrogen sulphites; a somewhat unstable *phenylhydrazone* of this substance, $C_6H_4Me{\cdot}C_3H_5{:}N_2HPh$, melting at 75°, a *nitro-derivative*, $NO_2{\cdot}C_6H_3Me{\cdot}C_3H_5O$, melting at about 60°, and the phenylhydrazine compound of the latter, $NO_2{\cdot}C_6H_3Me{\cdot}C_3H_5{:}N_2HPh$, melting at 127—128°, have also been prepared. S. B. A. A.

Action of Chlorine on Catechol and Orthamidophenol.

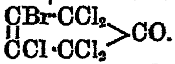
By T. ZINCKE and F. KÜSTER (*Ber.*, **23**, 2200—2225).—It has been previously shown (this vol., p. 754) that γγ-hexachlorohydroxypentenecarboxylic acid, on oxidation, gives a ketone (m. p. 92°) isomeric with the ketone (m. p. 31°) obtained from the corresponding βγ-acid (Abstr., 1888, 1278) in like manner; the course of the reaction depends, however, on the nature of the oxidising agent employed, as will be seen from the experiments described below.

γγ-Hexachloroketopentene (m. p. 92°) is obtained, together with about an equal quantity of a compound of the composition $C_{10}Cl_{10}O_3H_2$, when γγ-hexachlorohydroxypentenecarboxylic acid (m. p. 186°) is oxidised with chromic acid in the manner previously described in the case of the isomeric acid (m. p. 111°). The hot solution is diluted with water, and the two oxidation-products, which are precipitated, separated by recrystallisation from benzene, in which the ketone only is moderately easily soluble. γγ-Hexachloroketopentene is precipitated in crystals, together with traces of a substance melting at 173°, when chlorine is passed into a warm aqueous solution of the γγ-acid; the yield is almost theoretical. It is also formed when the γγ-acid is oxidised with chlorine in dilute acetic acid solution, or with sodium hypochlorite and glacial acetic acid, but oily byeproducts are also obtained in these reactions.

γγ-Hexachloroketopentene forms large, colourless, transparent, monosymmetric crystals, $a : b : c = 0{\cdot}60339 : 1 : 0{\cdot}73795$, $\beta = 64° 43'$, melts at 92°, and boils at 148° (75 mm.), and at 235·5° (740·5 mm.); it sublimes in plates, is readily volatile with steam, and has an odour recalling that of camphor and chloroform; it is readily soluble in benzene, chloroform, and ether, crystallises well from alcohol and glacial acetic acid, and separates unchanged from boiling concentrated nitric acid in colourless needles. It does not react with hydroxylamine, but it gradually combines with aniline in cold benzene solution, yielding a brown, amorphous substance; it is slowly acted on by sodium carbonate in alcoholic solution, yielding a resinous substance, which is precipitated on the addition of an acid. Alkalis convert it into resinous acids, even at the ordinary temperature; in the cold, a very small quantity of pentachloropentolic acid (pentachlorobutenecarboxylic acid, Abstr., 1888, 1278) and larger quantities of an unstable isomeric acid are produced.

γγ-Pentachlorobromoketopentene, C_5Cl_5BrO, is formed when an aqueous solution of the γγ-acid (10—15 grams) is heated with bromine (25—30 grams) and hydrobromic acid (20 grams) until no further action takes place, but part of the acid remains unchanged; the ketone, which is deposited from the cold solution in crystals, is separated by filtration, treated with light petroleum to free it from the unchanged acid, and the clear solution evaporated. It is best prepared by heating the γγ-acid with a slight excess of the theoretical quantity of sodium hypobromite in glacial acetic acid solution, the product being purified in the manner just described. It is also formed when the βγ-acid is oxidised with bromine or sodium hypobromite, a βγ-ketone of the composition C_5Cl_5BrO not being obtained under these conditions; it is best prepared from the βγ-acid by heating it at 100° in sealed tubes for 1—1½ hours with bromine (5 parts) and water (5 parts). The ketone obtained from the βγ-acid by oxidation with chlorine is identical with the compound (m. p. 31°) obtained by oxidation with chromic acid (Abstr., 1888, 1278), and the formation of a γγ-ketone could not be detected under these conditions.

Pentachlorobromoketopentene forms monosymmetric crystals, $a : b : c = 0{\cdot}60930 : 1 : 0{\cdot}75765$, $\beta = 64° 57\tfrac{1}{2}'$, identical in appearance with those of the hexachloro-compound; it melts at 102°, its sp. gr. is 2·159 at 15°, and it has an odour like that of the hexachloroketone, which it also resembles very closely in chemical behaviour. It dissolves in well-cooled soda, yielding the sodium salt of an unstable acid of the composition $C_5Cl_4Br{\cdot}COOH$ and a stable compound which seems to be a mixture of pentachloropentolic acid (m. p. 127°) and bromotetrachloropentolic acid; its behaviour with sodium carbonate and hydroxylamine is the same as that of the hexachloroketone, but it is not acted on by hydrocyanic acid, and it is not converted into the corresponding βγ-ketone on heating, decomposition taking place at the temperature required. Its constitution is expressed by the formula



$$\begin{matrix}CBr{\cdot}CCl_2\\ \|\\ CCl{\cdot}CCl_2\end{matrix}\!>CO.$$

When βγ-hexachloroketopentene is heated at 290—300°, it is partially converted into the γγ-ketone, the latter, under the same conditions, undergoing transformation into the βγ-compound; when the βγ-ketone is heated with hydrochloric acid and manganese dioxide at 120° in sealed tubes, it is almost completely converted into the isomeride.

γγ-Octochloropentene,  $\begin{matrix}CCl{\cdot}CCl_2\\ \|\\ CCl{\cdot}CCl_2\end{matrix}\!>CCl_2$ (this vol., p. 755), crystallises from light petroleum in thick, colourless prisms, melts at 41°, boils at 283°, and is readily soluble in the ordinary solvents; it is not acted on by alkalis, and it is only very slowly destroyed by concentrated nitric acid.

γγ-Hexachloro-α-hydroxypentene cyanide,  $\begin{matrix}CCl{\cdot}CCl_2\\ \|\\ CCl{\cdot}CCl_2\end{matrix}\!>C(OH){\cdot}CN$, is obtained when the γγ-ketone is treated with potassium cyanide in well-cooled alcoholic solution, and the salt thus produced decomposed with dilute hydrochloric acid. It crystallises from hot light petroleum in colourless needles, melts at 128°, and decomposes at about 150° into ketone and hydrogen cyanide; it is readily soluble in alcohol, ether, chloroform, benzene, and light petroleum, and it seems to crystallise unchanged from hot concentrated nitric acid, but it is decomposed by warm water, warm dilute hydrochloric acid. and boiling acetic anhydride. It dissolves unchanged in dilute alkalis, yielding the corresponding alkaline-derivative, and it is not converted into a hydroxy-acid when boiled with 10 per cent. soda, or when heated with hydrochloric or sulphuric acid in alcoholic solution. The *acetyl*-derivative, $C_5Cl_6(OAc)\cdot CN$, prepared by heating the cyanide with acetic chloride at 120—130°, crystallises from benzene in large, colourless, hexagonal prisms, melts at 96—97°, and is decomposed by boiling alkalis, water, and dilute hydrochloric acid, being converted into the ketone.

The *amide*,  $\left.\begin{array}{l}\mathrm{CCl\cdot CO}\\ \|\\ \mathrm{CCl\cdot CCl_2}\end{array}\right>\mathrm{C(OH)\cdot CO\cdot NH_2}$, is formed, with evolution of hydrogen chloride, when γγ-hexachloroketopentene is warmed for a short time with concentrated sulphuric acid. It separates from ether in long, colourless needles, melts at 198—200° with decomposition, and is very readily soluble in alcohol and ether, and moderately easily in benzene, but only sparingly in light petroleum; it crystallises unchanged from dilute hydrochloric acid and from concentrated nitric acid, and it dissolves in alkalis with evolution of ammonia.

Pentachloropentolamide, $CCl_2{:}CCl\cdot CCl{:}CCl\cdot CO\cdot NH_2$, is formed when γγ-hexachloroketopentene is dissolved in benzene, the solution saturated with anhydrous ammonia in the cold, and kept for 12 hours at the ordinary temperature (compare this vol., p. 755). It separates from a mixture of ether and light petroleum in compact crystals, and from a mixture of benzene and light petroleum in quadratic plates or prisms, melts at 116°, and is readily soluble in ether, benzene, and alcohol, but more sparingly in light petroleum; it dissolves in hot dilute soda with evolution of ammonia, and on acidifying the solution, pentachloropentolic acid (m. p. 127°) is precipitated in crystals.

The compound of the composition $C_5Cl_5H_3N_2O$ (compare this vol., p. 755), which is obtained by treating βγ-hexachloroketopentene with ammonia under the same conditions as those described in the case of the γγ-ketone, crystallises from a mixture of ether and light petroleum in large, colourless prisms, from hot benzene in rhombic plates melting at 118°, and from hot water in long needles melting at 127°. It is readily soluble in alcohol and ether, but only moderately easily in benzene, and sparingly in light petroleum; it dissolves in alkalis, yielding a solution which has a strong odour of carbylamine, but it is not acted on by boiling acetic anhydride, acetic chloride, nitrous acid, or warm concentrated sulphuric acid. Phosphoric chloride, at 180—190°, converts it into a very unstable, crystalline substance which contains phosphorus, and which is reconverted into the original compound when treated with water. F. S. K.

Alkylation of Formanilide. By W. J. Comstock (*Ber.*, 23, 2274—2275).—Silver formanilide reacts very readily with an ethereal solution of iodine, giving formopariodoanilide, C_7H_6NOI, and also with methyl iodide, yielding methylisoformanilide, NPh:CH·OMe. Since sodioformanilide reacts with methyl iodide to form methylformanilide, it must have the constitution NPhNa·CHO; silver formanilide, on the other hand, must have the constitution NPh:CH·OAg.

When dry silver succinimide is treated with methyl iodide, an oil, which boils at about the same temperature as methylsuccinimide, is obtained; this compound, unlike methylsuccinimide, combines with aniline in the cold, yielding a solid basic product.

A full account of the author's experiments will be published in the *American Chemical Journal*. F. S. K.

Phenylorthobenzylenediamine and Paratolylorthobenzylenediamine. By H. G. Söderbaum and O. Widman (*Ber.*, 23, 2187—2195).—*Orthamidobenzylparatoluidine*,

$$NH_2{\cdot}C_6H_4{\cdot}CH_2{\cdot}NH{\cdot}C_6H_4Me,$$

can be obtained by reducing the corresponding nitro-compound with zinc-dust and glacial acetic acid; it crystallises from alcohol in thin, quadratic plates, melts at 80·5°, and is readily soluble in benzene, chloroform, and alcohol, but almost insoluble in light petroleum. The *diacetyl*-derivative, $NHAc{\cdot}C_6H_4{\cdot}CH_2{\cdot}NAc{\cdot}C_6H_4Me$, prepared by boiling the base with acetic anhydride, crystallises in colourless plates, melts at 185—186°, and is sparingly soluble in ether and hot alcohol.

The authors tried repeatedly to prepare the paratolylbenzylene-ethenylamidine described by Lellmann and Stickel (Abstr., 1886, 793), but without success; when the acetyl-derivative of orthonitrobenzylparatoluidine (m. p. 65°) is reduced with tin and hydrochloric acid in glacial acetic acid, as described by Lellmann and Stickel, it yields very small quantities of a substance which is difficult to purify, so that the supposed amidine is most probably nothing but impure orthamidobenzyltoluidine.

Orthamidobenzylacetoparatoluidide, $NH_2{\cdot}C_6H_4{\cdot}CH_2{\cdot}NAc{\cdot}C_6H_4Me$, is obtained when pure nitrobenzylacetoparatoluidide is treated with zinc-dust and hydrochloric acid in cold alcoholic solution. It separates from alcohol in colourless crystals, melts at 99°, and is very readily soluble in cold benzene and warm alcohol, but more sparingly in light petroleum. When heated with concentrated hydrochloric acid at 100°, it is converted into orthamidobenzylparatoluidine (m. p. 80·5°).

Orthamidobenzylaniline, $NH_2{\cdot}C_6H_4{\cdot}CH_2{\cdot}NHPh$, can be prepared by heating orthonitrobenzyl chloride with aniline and reducing the product with zinc-dust and acetic acid; it crystallises from alcohol and benzene in colourless needles or prisms melting at 81—82°.

Orthamidobenzylbenzoylanilide, $NH_2{\cdot}C_6H_4{\cdot}CH_2{\cdot}NBzPh$, is obtained when orthonitrobenzylbenzoylanilide is reduced with zinc-dust and acetic acid. It crystallises from alcohol in short needles, melts at 115°, and is identical with the compound (m. p. 114·5°) described as phenylbenzylenebenzenylamidine by Lellmann and Stickel (*loc. cit.*). The *acetyl*-derivative, $C_{22}H_{20}N_2O_2$, prepared by boiling the base with acetic anhydride, separates from warm alcohol, in which it is readily soluble, in colourless crystals melting at 164—165°. F. S. K.

Derivatives of Orthoparadinitrophenylphenylhydrazine. By C. WILLGERODT and B. HERMANN (*J. pr. Chem.* [2], **42**, 126—133).—The authors have determined the molecular weights of nitronitroso- and dinitroso-azobenzene by Raoult's method, and have thus confirmed their constitutions as derivatives of azobenzene (Abstr., 1889, 1160).

Paratrinitroazobenzene, $NO_2·C_6H_4·N_2·C_6H_3(NO_2)_2$ [$NO_2 : N = 4 : 1$, and $(NO_2)_2 : N = 4 : 2 : 1$], is obtained by mixing dinitrophenylphenylhydrazine or orthoparadinitroazobenzene with fuming nitric acid (sp. gr. 1·52), warming the mixture on the water-bath, and pouring it into cold water; it crystallises in red needles which melt at 170° (uncorr.), and dissolve in hot organic solvents, but not in water. With fuming nitric acid and chromic acid, it yields an oxidation-product, agreeing with Klinger and Zuurdeeg's paratrinitroazoxybenzene (this vol., p. 761), but it melts at 133°, not 136—137°; this confirms the constitution of this trinitroazobenzene.

Orthoparatetranitroazobenzene, obtained by further nitrating paratrinitroazobenzene, crystallises in beautiful orange tables, which melt at 222° (uncorr.), and are insoluble in water, sparingly soluble in alcohol and ether, and freely soluble in benzene, glacial acetic acid, and chloroform.

Trinitronitrosoazobenzene is prepared by heating nitronitrosoazobenzene with fuming nitric acid and adding water; it forms crystals which melt at 224° (uncorr.), and dissolve sparingly in hot water, hot alcohol, and ether, but freely in glacial acetic acid, benzene, and chloroform. Its constitution is uncertain.

Dinitrodinitrosoazobenzene is obtained by warming dinitrosoazobenzene [1 : 2 : 4] with fuming nitric acid for some time, and adding water. It crystallises in short, yellow needles which melt at 238°.

When dinitrophenylphenylhydrazine (2 grams) is dissolved in chloroform and acted on by bromine (0·63 gram), white needles melting at 242° are obtained on subsequent evaporation of the chloroform and crystallisation of the residue. The analysis of these crystals leaves the composition in doubt, save that the substance is a monobrominated derivative. When excess of bromine is used, crystals which melt at 190° are obtained; this also is of uncertain composition, but is certainly a dibrominated derivative; the same substance is produced by acting on dinitroazobenzene with excess of bromine, so it must almost certainly be a dinitrodibromazobenzene. A. G. B.

Derivatives of Diphenylhydrazine and Methylphenylhydrazine. By R. STAHEL (*Annalen*, **258**, 242—251).—Diphenylhydrazine, prepared by the method described by Fischer (*Annalen*, **190**, 179), and purified by distillation under reduced pressure, crystallises from light petroleum in well-defined, monoclinic plates, melts at 34·5°, and boils at about 220° (40 to 50 mm.). It combines only slowly with the ordinary sugars in alcoholic solution at the ordinary temperature, but the reaction takes place more quickly on warming, sparingly soluble, crystalline hydrazones being formed.

Glucosediphenylhydrazone, $C_6H_{12}O_5{:}N_2Ph_2$, is prepared by boiling glucose with diphenylhydrazine in aqueous alcoholic solution for two hours; the alcohol is evaporated almost completely, ether added to precipitate the hydrazone, and the process repeated with the mother liquors; the yield is about 75 per cent. of the theoretical. It crystallises from hot water in small, colourless prisms, melts at 161—162°, and is readily soluble in hot water and alcohol, but almost insoluble in ether, benzene, and chloroform; it reduces Fehling's solution on boiling, and it is decomposed into its constituents by concentrated hydrochloric acid. The formation of this compound can be very conveniently employed for the detection of dextrose in presence of levulose.

Mannosediphenylhydrazone, $C_6H_{12}O_5{:}N_2Ph_2$, prepared in like manner, crystallises in small, colourless prisms, melts at 155°, and resembles the preceding compound in its properties.

Galactosediphenylhydrazone, $C_6H_{12}O_5{:}N_2Ph_2$, crystallises from hot water in colourless prisms, melts at 157°, and resembles the hydrazones described above in its behaviour with solvents.

Rhamnosediphenylhydrazone, $C_6H_{12}O_4{:}N_2Ph_2$, crystallises from hot water in colourless needles melting at 134°.

Furfuraldehyde diphenylhydrazone, $C_4H_3O\cdot CH{:}N_2Ph_2$, obtained by treating the aldehyde with the base, crystallises from dilute alcohol in yellowish needles, melts at 90°, and is readily soluble in alcohol and ether, but only sparingly in benzene, and insoluble in water; it dissolves in concentrated sulphuric acid, and in hydrochloric acid yielding a red solution, which turns dirty brown after a long time, whereas the solution in glacial acetic acid retains its red colour.

Salicylaldehyde diphenylhydrazone, $OH\cdot C_6H_4\cdot CH{:}N_2Ph_2$, prepared in like manner, crystallises from hot 80 per cent. alcohol in colourless needles, melts at 138·5°, and is readily soluble in ether and alcohol, but almost insoluble in water.

Diphenylthiocarbazinic acid, $NPh_2\cdot NH\cdot CS\cdot SH$, is deposited in well-defined golden prisms when a solution of diphenylhydrazine in carbon bisulphide is allowed to evaporate at the ordinary temperature; it melts at 109° with decomposition, is rather unstable, and is insoluble in water, but readily soluble in alcohol, ether, chloroform, and acetone. It dissolves unchanged in cold dilute soda, and in its alcoholic solution silver nitrate produces a yellow, mercuric chloride a violet-red, and ferric chloride a deep red precipitate. On distillation, it is decomposed into carbon bisulphide, hydrogen sulphide, and diphenylamine.

Dimethyldiphenylthiocarbazide, $CS(NH\cdot NPhMe)_2$, is obtained when methylphenylhydrazine is heated with carbon bisulphide for three hours at 100°. It separates from dilute alcohol in colourless crystals, melts at about 168° with decomposition, and is readily soluble in alcohol, but insoluble in water; it is not acted on by boiling dilute soda, but is completely decomposed by warm concentrated hydrochloric acid.

F. S. K.

Isomeric Oximes. By H. Goldschmidt (*Ber.*, **23**, 2163—2180; compare this vol., p. 251).—*Methylanisaldoxime*,

$OMe\cdot C_6H_4\cdot CH\vdots N\cdot OMe$,

is obtained when anisaldoxime (m. p. 61°) is treated with sodium methoxide and methyl iodide in methyl alcoholic solution at the ordinary temperature. It crystallises from light petroleum in transparent, seemingly quadratic plates, melts at 43°, boils at 246° (724 mm.), and has a peculiar, agreeable odour; it is very readily soluble in alcohol, ether, and benzene, but more sparingly in light petroleum. No precipitate is produced when hydrogen chloride is passed into its alcoholic solution, whereas those alkyl-derivatives of aldoximes in which the alkyl is directly combined with nitrogen always give a precipitate, and, moreover, when heated with hydriodic acid it yields ammonia, but not methylamine; these reactions prove that the methyl-group is in direct combination with oxygen.

Isoanisilaldoxime, prepared by Beckmann's method (this vol., p. 1121), melts at 133°, and can be converted into the isomeride by heating it for a short time above its melting point.

Carbanilidoisoanisaldoxime, $OMe\cdot C_6H_4\cdot CH\vdots N\cdot O\cdot CO\cdot NHPh$, is precipitated in yellowish plates, when phenylcarbimide is added to an ethereal solution of isoanisaldoxime. It melts at 80° with decomposition, and, like other carbanilido-derivatives of isoaldoximes, is very unstable; it decomposes spontaneously into diphenylcarbamide, anisonitrile, carbonic anhydride, and water, and when treated in benzene solution with a little hydrogen chloride it is converted into the much more stable isomeride melting at 82° (compare Goldschmidt, *loc. cit.*).

Methylisoanisaldoxime, $OMe\cdot C_6H_4\cdot CH\vdots N\cdot OMe$, can be obtained in small quantities as follows:—Isoanisaldoxime is treated with the theoretical quantity of sodium ethoxide and then with an alcoholic solution of silver nitrate; the silver salt, which is precipitated in a colourless condition but rapidly darkens, is washed consecutively with alcohol and ether, treated with methyl iodide in cold ethereal solution, and after some hours the clear solution evaporated. It can also be obtained, together with another compound, which seems to be the methyl-derivative of the constitution  $OMe\cdot C_6H_4\cdot CH<\begin{matrix}O\\ |\\ NMe\end{matrix}$, by treating anisaldoxime with sodium methoxide and methyl iodide; the two compounds are separated by distillation with steam. It is a colourless oil, distils unchanged at 245° when pure, and is volatile with steam. No precipitate is produced on passing hydrogen chloride into its ethereal solution. When kept for some hours with dilute hydrochloric acid, when treated with sodium hydrogen sulphite, or when boiled with a trace of iodine, it is converted into the solid isomeride (m. p. 43°).

Benzylanisaldoxime, prepared by treating anisaldoxime with sodium ethoxide and benzyl chloride, melts at 47° (compare Beckmann, *loc. cit.*); when warmed with hydriodic acid, it yields benzyl iodide, so that its constitution is expressed by the formula

$OMe\cdot C_6H_4\cdot CH.N\cdot OC_7H_7$.

Benzylisoanisaldoxime, melting at 103·5° (compare Beckmann, *loc. cit.*), gives benzylamine when heated with hydriodic acid; it has, therefore, the constitution  $\mathrm{OMe{\cdot}C_6H_4{\cdot}CH}<\!\begin{array}{l}\mathrm{O}\\ |\\ \mathrm{N{\cdot}C_7H_7}\end{array}$.

Isometanitrobenzaldoxime, $NO_2{\cdot}C_6H_4{\cdot}CH{:}N{\cdot}OH$, can be prepared by passing hydrogen chloride into an ethereal solution of metanitrobenzaldoxime (m. p. 118—119°), and decomposing the hydrochloride obtained in this way with sodium carbonate. It crystallises from ether, in which it is only sparingly soluble, in colourless needles melting at 116—118°.

Carbanilidometanitrobenzaldoxime, $C_{14}H_{11}N_3O_4$, prepared by treating the oxime with phenylcarbimide in ethereal solution, crystallises from alcohol in yellowish needles, melts at 105°, and is readily soluble in alcohol and ether.

Carbanilidometanitroisobenzaldoxime, $C_{14}H_{11}N_3O_4$, prepared in like manner from the isoaldoxime, crystallises in small needles, melts at 75° with decomposition, and is only sparingly soluble in ether; it decomposes spontaneously, and when hydrogen chloride is passed into its ethereal solution, it is converted into the isomeride (m. p. 105°).

Methylmetanitroisobenzaldoxime,  $\mathrm{NO_2{\cdot}C_6H_4{\cdot}CH}<\!\begin{array}{l}\mathrm{O}\\ |\\ \mathrm{NMe}\end{array}$, is formed together with small quantities of the isomeride (m. p. 69°) when metanitroisobenzaldoxime is treated with sodium methoxide and methyl iodide at the ordinary temperature; the whole is submitted to distillation with steam to separate the isomeride, the residue rendered alkaline, extracted with ether, and the ethereal solution evaporated. It crystallises in yellow prisms, melts at 117°, and is only moderately easily soluble in alcohol and ether; hydrogen chloride precipitates from its ethereal solution a colourless salt, and when heated with hydriodic acid it gives methylamine.

Methylmetanitroisobenzaldoxime, $NO_2{\cdot}C_6H_4{\cdot}CH{:}N{\cdot}OMe$, can be obtained by treating the silver-derivative of the isoaldoxime, prepared by precipitating a solution of the sodium-derivative with silver nitrate, with methyl iodide in ethereal solution at the ordinary temperature. It crystallises from ether, alcohol, and benzene in almost colourless needles, melts at 69°, and is more sparingly soluble in ether and benzene than the isomeride (m. p. 63—63·5°) which has been previously prepared by Gabriel (*Ber.*, 15, 3061); that the two compounds are not identical was proved by a crystallographic examination.

Benzylmetanitroisobenzaldoxime,  $\mathrm{NO_2{\cdot}C_6H_4{\cdot}CH}<\!\begin{array}{l}\mathrm{O}\\ |\\ \mathrm{N{\cdot}C_7H_7}\end{array}$, prepared by treating the isoaldoxime with sodium ethoxide and benzyl chloride, crystallises from hot alcohol in yellow plates or needles, melts at 148°, and is sparingly soluble in cold ether and alcohol. It is decomposed by hydriodic acid with liberation of benzylamine, and when hydrogen chloride is passed into its ethereal solution a colourless precipitate is produced. The benzyl-derivative of metanitrobenzaldoxime was not obtained in a pure condition.

Methylcuminaldoxime, $C_6H_4Pr{\cdot}CH{:}N{\cdot}OMe$, prepared from cuminaldoxime (m. p. 58°), is a colourless liquid boiling at 245—246°

(705 mm.); the corresponding benzyl-derivative is a non-volatile oil.

Isocuminaldoxime, $C_{10}H_{13}NO$, crystallises from ether in small, colourless prisms, melts at 112°, and is more sparingly soluble in ether than cuminaldoxime. The *carbanilido*-derivative,

$$C_6H_4Pr\cdot CH{:}N\cdot O\cdot CO\cdot NHPh,$$

crystallises in small needles melting at 103° with decomposition.

The author's experiments show conclusively that both oximes and iso-oximes can form alkyl-derivatives of the constitution $X\cdot CH{:}N\cdot OR$; this fact proves that Beckmann's view of the isomerism of oximes is not correct. The author agrees with Hantzsch and Werner (this vol., p. 348), that the two forms are stereochemically isomeric, and have the constitution  $\begin{matrix}X\cdot CH\\ \Vert\\ RO\cdot N\end{matrix}$ and  $\begin{matrix}X\cdot CH\\ \Vert\\ N\cdot OR\end{matrix}$ respectively; since the carbanilido-derivatives of the iso-oximes are much more readily converted into nitriles than the corresponding derivatives of the normal oximes, the hydrogen-atom and the CO·NHPh-group must be nearer together in the iso- than in the normal compounds; it follows, then, that carbanilido- and carbanilidoiso-benzaldoxime have the constitution

$$\begin{matrix}Ph\cdot CH\\ \Vert\\ NHPh\cdot CO\cdot O\cdot N\end{matrix}$$

and

$$\begin{matrix}Ph\cdot CH\\ \Vert\\ N\cdot O\cdot CO\cdot NHPh\end{matrix}$$

respectively, and the aldoximes themselves are analogously constituted, a conclusion which is in accordance with Hantzsch and Werner's view.

Carbanilidoisobenzaldoxime is not converted into the isomeride by pure phenylcarbimide; the intramolecular change previously observed must therefore have been due to some impurity, probably hydrochloric acid. The intramolecular change observed by Beckmann (*loc. cit.*) which takes place when benzaldoxime is treated with phenylcarbimide, is probably due to the same cause.

That phenylcarbimide is a very suitable agent for determining the constitution of compounds such as the isomeric oximes, is proved by the above experiments, and V. Meyer's statement, that it is prone to bring about intramolecular change, is not correct. F. S. K.

Stereochemical Isomerism of Asymmetrical Monoximes. By A. HANTZSCH (*Ber.*, 23, 2322—2325).—This isomerism is shown to be due to the asymmetry of the molecule. A list of compounds of the general formula  $\begin{matrix}X\cdot C\cdot Y\\ \Vert\\ RO\cdot N\end{matrix}$ and  $\begin{matrix}X\cdot C\cdot Y\\ \Vert\\ N\cdot OR'\end{matrix}$, which exhibit the isomerism is then given. In these X and Y are displaced by the groups C_6H_5, C_4H_3S (from thiophen), C_4H_3O (from furfuran), $C_6H_4Cl(p)$, $C_6H_4Me(p)$, $C_6H_4\cdot OMe(p)$, H, OH, CO, COOH, and CNOH. The displacement of X or Y by an alcoholic radical, such as methyl, appears to prevent the occurrence of stereochemical isomerism C. F. B.

Isomeric Oximes of Unsymmetrical Ketones and the Configuration of Hydroxylamine. By K. AUWERS and V. MEYER (*Ber.*, 23. 2403—2409).—The researches of the authors on the oximes of bromo- and chloro-benzophenone (compare this vol., p. 1144), together with the recent investigations of Hantzsch and Werner on the oximes of unsymmetrical ketones, have shown that the isomerism of these compounds, and also of the benzil-oximes, cannot be explained by any assumption of structural dissimilarity. The real reason must therefore be sought, either in the nitrogen itself, or in the nature of the hydroxylamine-group. Hantzsch and Werner have advanced the former hypothesis, whilst the authors consider the latter to be the true explanation. Assuming the correctness of the theories of Van't Hoff and Wislicenus regarding the arrangement of atoms in space, the combined effect of the attraction of the nitrogen and oxygen on the hydroxylic hydrogen of hydroxylamine would cause it to be in a plane different from that occupied by the remaining atoms in the molecule. This hypothesis suffices to explain all observed facts; unsymmetrical oximes would therefore exist in two forms,  $\overset{a}{\underset{b}{\mathrm{C}}}{:}\mathrm{N}\overset{\mathrm{H}}{\mathrm{O}}$ and  $\overset{a}{\underset{b}{\mathrm{C}}}{:}\mathrm{N}{\cdot}\underset{\mathrm{H}}{\mathrm{O}}$. The difference between this theory and that of Hantzsch and Werner is shown by the two formulæ

$$\mathrm{C}{=}\overset{\mathrm{OH}}{\mathrm{N}}$$

and

$$\mathrm{C}{=}\mathrm{N}{-}\overset{\mathrm{H}}{\mathrm{O}}.$$

(H. & W.) (A. &. M.)

The formation of oximes by the action of nitrous acid is readily accounted for on the ground of its being a substituted hydroxylamine; moreover, the fact that no case of geometrical isomerism has ever been observed in the azo-, azoxy-, and imido-compounds tells in favour of this theory. On the other hand, the authors point out that no optically active hydroxylamine-derivatives have yet been prepared, although their existence is indicated by this hypothesis; the same objection may, however, be urged against the theory of Hantzsch and Werner.

J. B. T.

A Second Benzoïnoxime. By A. Werner (*Ber.*, **23**, 2333—2336).—The benzoïnoxime hitherto known, melting at 151°, has always been prepared with the aid of heat. When, however, a solution of hydroxylamine hydrochloride (1 mol.) is added to benzoïn (1 mol.), in minute crystals, suspended in dilute alcohol, the mixture neutralised with sodium carbonate, a solution of sodium hydroxide (1 mol.) then added, and the whole allowed to remain for several days at the ordinary temperature, the benzoïn slowly dissolves, and if the mixture is now poured into water and the whole acidified with acetic acid, it turns milky, and a substance separates which after a day or two gradually solidifies to a mass of crystals; these, when washed with ether, dissolved in alcohol, and reprecipitated with water, yield a new *β-benzoïnoxime* in white needles melting at 95—99°. By Raoult's method it was shown that both this and the ordinary α-oxime have the formula $C_{14}H_{13}NO_2$. The new oxime is decomposed into benzoïn and hydroxylamine when heated with alcoholic hydrochloric acid, and it can be converted into the α-isomeride; this is best effected by boiling it with dilute alcohol containing a little alkali.

C. F. B.

Amidoximes. By P. HOCHHEIM (*Inaugural Dissertation*, *Chem. Centr.*, 1890, i. 939).—*Anisylnitrile*, $C_7H_7O{\cdot}CN$, prepared from copper cyanide and diazoanisyl hydrochloride solution, boils at 255—256°. *Anisylamidoxime*, $C_7H_7O{\cdot}C(NOH){\cdot}NH_2$, melting point 122°, is prepared from the nitrile by the action of hydroxylamine. Its solution is coloured blood-red by ferric chloride; with Fehling's solution, it forms a dirty-green copper salt, and it reduces ammonia silver solution; the hydrochloride melts at 168°, the platinochloride at 196°, and the copper salt, $C_7H_7O{\cdot}C(NO{\cdot}Cu{\cdot}OH){\cdot}NH_2$, at 212°.

Anisylazoximeethenyl,  $C_7H_7O{\cdot}C\!\left\langle{}^{NO}_{N}\right\rangle\!CMe$, melting at 116°, is prepared from the amidoxime by the action of acetic anhydride or acetic chloride. With bromine, a monobrominated compound and a dibrom-additive compound are obtained, the former melting at 75° and the latter at 110°. With succinic anhydride, anisylamidoxime forms *anisylazoximepropenyl-ω-carboxylic acid*,

$$C_7H_7O{\cdot}C\!\left\langle{}^{NO}_{N}\right\rangle\!C{\cdot}CH_2CH_2{\cdot}COOH + H_2O,$$

which softens at 128°, and melts at 131°. The lead salt was analysed. *Chloralanisylamidoxime*, $C_7H_7O{\cdot}C(NOH)(NH_2),C_2HCl_3O$, is prepared by heating its components together; it melts at 139°. *Anisylimidoximecarbonyl*,  $C_7H_7O{\cdot}C\!\left\langle{}^{NO}_{NH}\right\rangle\!CO$, melting point 195°, is prepared from anisylamidoxime and ethyl chlorocarbonate. The corresponding *thio*-compound is prepared by heating the amidoxime with carbon bisulphide; it melts at 125—126°. *Anisyluramidoxime*, $C_7H_7O{\cdot}C(NOH){\cdot}NH{\cdot}CONH_2$, melting at 136° with decomposition, is prepared from anisylamidoxime hydrochloride and potassium cyanate. *Anisylphenyluramidoxime*, $C_7H_7O{\cdot}C(NOH){\cdot}NH{\cdot}CO{\cdot}NHPh$, prepared by the action of phenyl isocyanate (carbanil), melts at 136°, and is converted by the action of acetic anhydride and sodium acetate into anisylazoximeethenyl, whilst glacial acetic acid converts it into diphenylcarbamide and anisylamidoxime. Phenyl thiocarbimide combines with anisylamidoxime, forming a compound of the formula $C_{15}H_{13}N_3SO$, which the author has provisionally named *anhydroanisylphenylthiouramidoxime*. With mercuric oxide, only diphenylthiocarbamide could be obtained from it; with nitric acid a dinitro-derivative, melting at 206°, is obtained. J. W. L.

Constitution of Eurhodine, Induline, and Allied Dyes. By F. KEHRMANN (*Ber.*, 23, 2446—2454).—*Quinoneimides and Amidoquinones.*—On treating a dilute solution of the sodium-derivative of tetrahydroxyquinone with an orthophenyldiamine salt, and adding acetic acid, a compound separates in greenish-brown crystals; it is the analogue of the tolueneazine prepared by Nietzki and Kehrmann (compare Abstr., 1887, 473, and 1888, 263), and has the formula  $C_6H_4\!\left\langle{}^{N-}_{NH}\right\rangle\!C_6(OH)_3O$ [N : NH·O = 2 : 3 : 5]. It is very sparingly soluble in organic solvents, and rapidly oxidises on exposure to air, forming dihydroxyquinonephenazine; it dissolves in dilute mineral acids with a dark olive-green colour. By careful oxidation, the corresponding rhodizonic acid-derivative is obtained, insoluble in ammonia, but soluble in alkaline hydroxides with a violet-blue colour. Chloroparadihydroxyquinone reacts with orthophenylenediamine in a similar manner; after purification, the product crystallises from glacial acetic acid in concentric, garnet-red needles; it has the formula

$$C_6H_4<\genfrac{}{}{0pt}{}{N—}{NH}>C_6HCl(OH)O\ [Cl : H : O : OH = 1 : 4 : 5 : 6],$$

and is a feeble acid, uniting with alkaline hydroxides and carbonates to form reddish-yellow, soluble salts. The compound also combines with acids, but the salts are very unstable, and are entirely dissociated on adding water. With concentrated sulphuric acid, a dirty-green colour is produced, which changes to reddish-brown on dilution. The *hydrochloride* crystallises in long, brownish-red needles. This compound is undoubtedly analogous to the dihydroxyphenazine prepared by O. Fischer and Hepp (compare this vol., p. 800). Dichloroparadihydroxyquinone, nitroparadihydroxyquinone, and certain allied hydroxyquinones do not condense with orthophenylenediamine, toluylenediamine, or naphthalenediamine, but simply combine to form the respective salts, which may be recrystallised without decomposition. α-Naphtheurhodol is prepared by warming sodium hydroxynaphthaquinone with an orthophenylenediamine salt, in presence of acetic acid; the product is purified by treatment with sodium hydroxide solution, and the salt decomposed with acetic acid; it crystallises from glacial acetic acid in needles, and is identical with the compound obtained by Fischer and Hepp (*loc. cit.*) from amido-1 : 2-naphthaphenazine; the formula should therefore be

$$C_6H_4<\genfrac{}{}{0pt}{}{—N}{NH}>C_{10}H_5O,$$

instead of $C_6H_4<\genfrac{}{}{0pt}{}{N}{N}>C_{10}H_5{\cdot}OH$. α-Amidonaphthaphenazine is prepared by heating a concentrated alcoholic solution of hydroxynaphthaquinone and orthophenylenediamine hydrochloride in molecular proportion on the water-bath for 15 minutes. The solution becomes red, and solidifies to a mass of slender, red needles of the hydrochloride; the free base, $C_6H_4<\genfrac{}{}{0pt}{}{—N}{NH}>C_{10}H_5{:}NH$, is liberated by the action of ammonia; it has previously been obtained by Fischer and Hepp (*loc. cit.*) from benzeneazonaphthylamine and orthophenylenediamine. The formation of this compound proves definitely that, apart from possible tautomerism, hydroxynaphthaquinoneimide is represented by the formula $C_{10}H_5O(OH)(NH)$ [O : OH : NH = 1 : 2 : 4].

J. B. T.

Two Stereochemically Isomeric Derivatives of Furfuraldoxime. By A. WERNER (*Ber.*, 23, 2336—2339).—Furfuraldoxime was converted into its benzyl-derivative by the method of Japp and Klingemann. The product crystallised in small plates melting at 88°. When boiled with hydriodic acid, no benzyl iodide is formed, but when the mixture is heated at 180°, a small amount of benzylamine is obtained.

The formula of the benzyl-derivative is, therefore,  $\mathrm{O}<\begin{matrix}\mathrm{CH\cdot C_4H_3O}\\ |\\ \mathrm{N\cdot CH_2Ph}\end{matrix}$. This is confirmed by its synthesis from furfuraldehyde and β-benzylhydroxylamine; the latter being prepared from the benzyl-derivative of isobenzaldoxime, melting at 110° (which was incidentally shown by Raoult's method to have a molecular weight corresponding with the formula  $\mathrm{O}<\begin{matrix}\mathrm{CPh}\\ |\\ \mathrm{N\cdot CH_2Ph}\end{matrix}$), by neutralising it in aqueous solution with soda. When the above benzyl-derivative of furfuraldoxime is dissolved in ether, and hydrogen chloride passed in, and the hydrochloride thus formed is treated with soda, an isomeric benzyl-derivative is obtained, which crystallises from ether in long, shining needles melting at 65°. These, when allowed to remain. lose their transparency, and are converted into the isomeric modification melting at 88°. It is said to be a case of geometrical isomerism. C. F. B.

Oxazolines. By S. Gabriel and T. Heymann (*Ber.*, 23, 2493—2502).—Bromethylbenzamide is rapidly dissolved in hot water, the equivalent quantity of sodium hydroxide immediately added, and the solution distilled in a current of steam; the distillate is extracted with ether, and on evaporation, *μ-phenyloxazoline*,  $\begin{matrix}\mathrm{CH_2\cdot O}\\ |\\ \mathrm{CH_2\cdot N}\end{matrix}>\mathrm{CPh}$, is obtained; it is a colourless, strongly refractive liquid, boiling at 242—243°, and is miscible with alcohol, ether, and, to a less degree, with water. The yield is 50 per cent. of the theoretical. The same compound is also formed by the action of dilute aqueous sodium hydroxide, or alcoholic potash, on bromethylbenzamide.

The *picrate* is deposited in yellow needles melting at 177°. The *platinochloride* crystallises in orange-yellow needles. The *dichromate*, $(C_9H_9NO_2)_2,H_2Cr_2O_7$, forms yellowish-red needles; the *ferrocyanide* is precipitated as a yellowish-green, crystalline powder. On warming phenyloxazoline with excess of hydrobromic acid, bromethylbenzamide is regenerated; but if the *base* is in slight excess, and the solution is boiled for some time, *amidoethyl benzoate hydrobromide*, $OBz\cdot CH_2\cdot CH_2\cdot NH_2,HBr$ (m. p. 142—143°), is produced; it is also obtained by boiling bromethylbenzamide with water; its constitution is shown by the formation of benzoylglycol by the action of potassium nitrite; this compound has been previously described (compare Abstr., 1889, 1134) as hydroxyethylbenzamide,

$$OH\cdot CH_2\cdot CH_2\cdot NHBz,$$

but the above results show this to be incorrect With an equivalent quantity of hydrochloric acid, phenyloxazoline yields *β-amidoethylbenzoate hydrochloride*, crystallising from alcohol, on the addition of ethyl acetate, in flat needles which melt at 133—135°. With excess of hydrochloric acid, the oxazoline yields, *β-chlorethylbenzamide*, $CH_2Cl\cdot CH_2\cdot NHBz$, crystallising from light petroleum or water in needles melting at 102°.

$\beta\mu$-Methylphenyloxazoline,  $\begin{matrix}\mathrm{CHMe\cdot O}\\ |\\ \mathrm{CH_2—N}\end{matrix}>\mathrm{CPh}$, is obtained from

β-bromopropylbenzamide by methods similar to those employed for the preparation of phenyloxazoline, and also by the action of alcoholic potassium hydrosulphide; it is a clear, colourless liquid, boiling at 243—244° under a pressure of 750 mm. The *platinochloride* is orange-yellow; the *picrate* melts at 167°; the *chromate* is precipitated as an oil which quickly crystallises; the *ferrocyanide* forms a greenish-yellow, crystalline powder. With excess of hydrobromic acid, the oxazoline is reconverted into β-bromopropylbenzamide. With excess of hydrochloric acid, *β-chloropropylbenzamide*,

$$CHMeCl{\cdot}CH_2{\cdot}NHBz,$$

is formed, crystallizing from light petroleum in small needles, melting at 72—73°. *β-amidopropyl benzoate hydrobromide*,

$$NH_2{\cdot}CH_2{\cdot}CHMe{\cdot}OBz.HBr,$$

is prepared by boiling an aqueous solution of β-bromopropylbenzamide, or a mixture of the oxazoline hydrobromic acid in molecular proportion; it crystallises from glacial acetic acid in colourless needles melting at 132—133°. On heating this compound with potassium hydroxide, β-hydroxypropylbenzamide (m. p. 92—93°) is formed. No corresponding reaction of amidoethyl benzoate was observed. With potassium nitrite, benzoylpropylene glycol is obtained. The free *base* is prepared by adding an alkali to the hydrobromide; it is a colourless, viscid liquid, readily miscible with water. The *picrate* crystallises in flat needles melting at 188—189°. The *platinochloride* is deposited from hot water in flat yellowish needles. μ-Methyloxazoline picrate has previously been prepared (*loc. cit.*), the yield is slightly larger if bromethylamine hydrobromide is boiled for 15 minutes with an equal weight of acetic anhydride, and treated with a solution of sodium picrate. The product obtained on boiling this compound with water is the picrate of *amidoethyl acetate*, $NH_2{\cdot}CH_2{\cdot}CH_2{\cdot}OAc$, not hydroxyethylacetamide as previously stated.

J. B. T.

Tetraphenyltetracarbazone. By J. Culmann (*Annalen*, 258, 235—242).—The compound (m. p. 137°) prepared by Hess (Abstr., 1886, 547) by treating bromacetophenone with phenylhydrazine has the molecular formula $C_{28}H_{24}N_4$, as is proved by molecular weight determinations in benzene solution; the experiments described below show that it has most probably the constitution

$$\begin{array}{l}CH_2{\cdot}CPh{:}N{\cdot}NPh\\ |\qquad\qquad\quad\;\; |\\ CH_2{\cdot}CPh{:}N{\cdot}NPh\end{array}$$

and it is named *tetraphenyltetracarbazone* by the author, the term *tetracarbazone* being applied to the ring $C_4H_4N_4$.

When tetraphenyltetracarbazone (1 part) is dissolved in a saturated ice-cold alcoholic solution (5 parts) of hydrogen chloride, it is converted into a compound of the composition $C_{22}H_{18}N_2$, aniline, and small quantities of a base of the composition, $C_{22}H_{17}N_3$. After keeping for 10 minutes, the solution is poured into ice-cold water, the precipitate separated by filtration, washed with cold alcohol to free it from resinous products, and the residue crystallised from hot alcohol.

The compound of the composition $C_{22}H_{18}N_2$ separates from the alcoholic solution, on cooling, in yellow needles, melts at 116°, and decomposes at a higher temperature; it is insoluble in water, but moderately easily soluble in hot alcohol and glacial acetic acid. It is probably the phenylhydrazine-derivative of diphenacyl, as, on oxidation with potassium dichromate and sulphuric acid, it yields a large quantity of benzoic acid, and when warmed with 30 per cent. sulphuric acid it is decomposed into dibenzoylethane (phenacylacetophenone), identical with the compound (m. p. 144°) obtained by Claus and Werner (Abstr., 1887, 827) and named diphenacyl by Kraft and Paal (Abstr., 1889, 147); a substance, melting at 229°, the composition of which was not determined, is also formed in very small quantities in this decomposition.

The base of the composition $C_{22}H_{17}N_3$ is gradually deposited from the acid alcoholic mother liquors obtained in the decomposition of tetraphenyltetracarbazone, in the form of the *hydrochloride*,

$$C_{22}H_{17}N_3,HCl.$$

This salt crystallises from hot dilute hydrochloric acid in colourless, slender needles, melts above 300°, and is moderately easily soluble in hot alcohol and water. The *nitrate* crystallises in plates. The free *base* is an orange-yellow, amorphous compound, and has perhaps the constitution

$$\begin{array}{l}CH\cdot CPh{:}N\\ \|\\ CH\cdot CPh{:}N\end{array}\!\!>NPh.$$

All attempts to prepare the two decomposition-products of tetraphenyltetracarbazone synthetically from diphenacyl, or its dihydrazone, were unsuccessful. F. S. K.

Thiophenylmethylpyrazolone. By A. MICHAELIS (*Ber.*, 23, 2476—2478).—The compound obtained by the action of phenylhydrazine on ethyl thioacetoacetate (compare this vol., p. 582) has the formula $C_{20}H_{18}O_2N_4S$, instead of $C_{20}H_{22}O_4N_4S$ as stated, and is identical with the thiophenylmethylpyrazolone described by Buchka and Sprague (compare this vol., p. 796). J. B. T.

Aromatic Mercury Compounds. By A. MICHAELIS and J. RABINERSON (*Ber.*, 23, 2342—2346).—*Mercurodimethylaniline chloride*, $HgCl\cdot C_6H_4\cdot NMe_2$, is prepared by mixing alcoholic solutions of mercuric chloride and mercurodimethylaniline; the compound is immediately deposited in white, lustrous plates melting at 225° with decomposition; it is soluble in chloroform, and in cold dilute hydrochloric acid, from which it is precipitated unchanged by sodium carbonate; it is decomposed into its components on warming with dilute acid. The same compound may be obtained by treating a benzene solution of mercurodimethylaniline with hydrochloric acid. *Mercurodimethylaniline bromide*, $HgBr\cdot C_6H_4\cdot NMe_2$, is prepared in a manner similar to the chloride, and melts at 226°. The *iodide*, $HgI\cdot C_6H_4\cdot NMe_2$,.crystallises in colourless plates melting at 195°.

Paramercurodianisoil, $Hg(C_6H_4\cdot OMe)_2$, prepared from parabromanisoïl, crystallises from benzene in slender, white needles melting at 202°, is readily soluble in chloroform, and sublimes when carefully heated; the yield is about 40 per cent. *Mercuranisoïl chloride*, $HgCl\cdot C_6H_4\cdot OMe$, is obtained in the same manner as the dimethylaniline-derivative; it crystallises in colourless, lustrous plates melting at 239°. The corresponding *bromide*, $HgBr\cdot C_6H_4\cdot OMe$, melts at 187°; and the *iodide*, $HgI\cdot C_6H_4\cdot OMe$, at 227°. *Mercuranisoïl acetate*, $OAc\cdot Hg\cdot C_6H_4\cdot OMe$, is formed by treating mercurodianisoïl with glacial acetic acid; it crystallises from alcohol in needles melting at 176·5°. *Mercuranisoïl oxide* $O(Hg\cdot C_6H_4\cdot OMe)_2$, is prepared by warming any one of the above haloïd compounds with sodium carbonate solution; the white powder which is obtained on cooling is washed with water, and recrystallised from alcohol; it is deposited in small, white, slender needles melting at 177°; it is very sparingly soluble in water, but dissolves readily in warm sodium carbonate solution. The aqueous solution has an alkaline reaction, but it does not combine with carbonic anhydride on exposure to the air.

J. B. T.

A Product of the Condensation of Ethyl Cyanacetate and Benzaldehyde. By J. T. Carrick (*J. pr. Chem.* [2], **42**, 159—160).—In the presence of sodium ethoxide (0·2 gram of sodium), benzaldehyde (5 grams) and ethyl cyanacetate (5 grams) readily undergo condensation, brilliant crystals of the empirical composition $C_{12}H_{11}NO_3$ separating out. An oily product is also formed, but it has not been investigated.

The condensation-product is decomposed with difficulty by strong sulphuric or nitric acid; when heated with strong hydrochloric acid at 150°, it yields benzaldehyde and carbonic anhydride. Aqueous alkalis decompose it in the cold with formation of benzaldehyde. Alcoholic methylamine forms with it a compound, $(C_{20}H_{12}N_2O_2)_2NMe$; alcoholic ammonia has a similar action; aqueous ammonia dissolves it, and acids precipitate a nitrogenous substance from the solution.

A. G. B.

Vanillin from Rosa canina. By Schneegans (*J. Pharm.* [5], **22**, 115; from *J. Pharm. Elsass-Loth.*, 1890, 97).—The powdered seeds are extracted by means of ether; part of the ether is separated by distillation, and the residue is agitated with hydrogen sodium sulphite solution saturated with sulphurous anhydride. To the aqueous solution, treated repeatedly with ether to remove fatty compounds, is next added excess of dilute sulphuric acid; the sulphurous anhydride set free is removed by a current of air, and ether is again added to extract a brown oil which, after some days, becomes a mass of crystals. These crystals, decolorised by charcoal, give the characteristic reactions of vanillin; the yield is exceedingly small, only about 1 in 10,000.

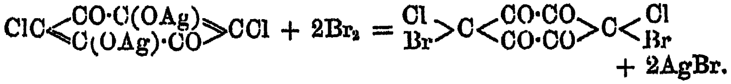
J. T.

Constitution of Quinone. By J. U. Nef (*J. pr. Chem.* [2], **42**, 161—188).—It has been shown by Stenhouse (this Journ., 1870, p. 8) that chloranilic acid is readily converted into the ethyl salt, $C_6Cl_2O_2(OEt)_2$, by treating silver chloranilate with ethyl iodide. This compound has all the properties of a quinone, and must contain the ethyl-groups combined with the oxygen, as otherwise its constitution would be represented by the formula $\begin{matrix}\mathrm{Et}\\ \mathrm{Cl}\end{matrix}{>}\mathrm{C}{<}\begin{matrix}\mathrm{CO{\cdot}CO}\\ \mathrm{CO{\cdot}CO}\end{matrix}{>}\mathrm{C}{<}\begin{matrix}\mathrm{Et}\\ \mathrm{Cl}\end{matrix}$, in which case it must, on reduction, take up four atoms of hydrogen. Experiment has, however, shown that, under these circumstances, two, and only two, atoms of hydrogen can be taken up, the compound formed being *ethyl hydrochloranilate*, $C_6Cl_2(OH)_2(OEt)_2$, which has previously been prepared by Kehrmann (this vol., p. 136). It is not attacked by sodium amalgam, even when digested with it for six hours on the water-bath, and is converted on boiling with acetic anhydride into the diacetyl-compound, $C_6Cl_2(OAc)_2(OEt)_2$, which crystallises from alcohol in colourless, four-sided prisms melting at 172°, and volatilising without decomposition.

Diacetylchloranilic acid, $C_6Cl_2O_2(OAc)_2$, is readily obtained by adding an ethereal solution of acetic chloride to silver chloranilate suspended in ether free from alcohol and water. It crystallises from ether or anhydrous benzene in yellow needles, melts at 182·5°, and distils unchanged. Its alcoholic solution speedily undergoes decomposition in presence of traces of water.

These results show conclusively that chloranilic acid contains two hydroxyl-groups. It is, however, somewhat surprising that the hydrogen-atoms cannot be removed by oxidation, and it would appear possible that the two pairs of hydroxyl-groups in hydrochloranilic acid have a different value. If such were the case, we should then get two different paradichlorodimethoxydiethoxybenzenes by the ethylation of dimethyl hydrochloranilate, and by the methylation of diethyl hydrochloranilate respectively, whereas it is found that one and the same compound is obtained in both cases. This crystallises in long, colourless needles which melt at 103°, and are very soluble in organic solvents. On oxidation, it gives a mixture of methyl and ethyl chloranilates.

By the action of bromine in dry carbon bisulphide solution on silver chloranilate, *dibromodichlorotetraketohexamethylene* is formed, the following reaction taking place:—



$$\mathrm{ClC}{<}\begin{matrix}\mathrm{CO{\cdot}C(OAg)}\\ \mathrm{C(OAg){\cdot}CO}\end{matrix}{>}\mathrm{CCl} + 2\mathrm{Br_2} = \begin{matrix}\mathrm{Cl}\\ \mathrm{Br}\end{matrix}{>}\mathrm{C}{<}\begin{matrix}\mathrm{CO{\cdot}CO}\\ \mathrm{CO{\cdot}CO}\end{matrix}{>}\mathrm{C}{<}\begin{matrix}\mathrm{Cl}\\ \mathrm{Br}\end{matrix} + 2\mathrm{AgBr}.$$

That the bromine does not simply take the place of the silver with formation of a bromoxyl-derivative is proved by the fact that the same compound is obtained by the action of chlorine on silver bromanilate. Dibromodichlorotetraketohexamethylene crystallises in pale-yellow, flat, hygroscopic needles, which when heated quickly in small quantities sublime unchanged, but commence to decompose at 110° when slowly heated. Its solution in carbon bisulphide has a slight green fluorescence. It does not give characteristic compounds with phenylhydrazine or orthodiamidotoluene, and is very readily decomposed by water, with evolution of carbonic anhydride and formation of pentamethylene-derivatives. On reduction with sulphurous acid, it is reconverted into chloranilic acid.

Tetrachlorotetraketohexamethylene, $\mathrm{Cl_2C}{<}\begin{matrix}\mathrm{CO{\cdot}CO}\\ \mathrm{CO{\cdot}CO}\end{matrix}{>}\mathrm{CCl_2}$, is obtained in a similar manner by the action of chlorine on silver chloranilate, and crystallises in long, pale-yellow needles, which are not reduced to chloranilic acid by the action of sulphurous acid. The chlorine-atoms are therefore more firmly combined than the bromine-atoms.

Tetrabromotetraketohexamethylene,  $Br_2C<\substack{CO\cdot CO\\CO\cdot CO}>CBr_2$. To prepare this compound, silver bromanilate is treated with bromine in the manner already described. It crystallises in flat, pale-yellow needles, which cannot be sublimed without decomposition, even when quickly heated. When water is poured on to it, a vigorous effervescence takes place, carbonic anhydride being evolved, and a compound having the composition $C_5Br_3O_3H$ remaining in solution, which is identical with the compound described by Hantzsch as tribromotriketopentamethylene (Abstr., 1888, 1190). It behaves, however, as a monobasic acid, and the author therefore regards it as *tribromhydroxydiketodihydropentene*,  $\begin{matrix}CO\cdot CBr\\ | \\ CO\cdot CBr_2\end{matrix}>C\cdot OH$. He further believes that tetrabromotetraketohexamethylene is always the first intermediate product in the formation of pentamethylene-derivatives from the anilic acids; that it has not previously been isolated is due to the fact that the reaction has been carried out in aqueous solution, in which this compound is immediately decomposed. A tetrabromotetraketohexamethylene has indeed been described by Hantzsch, but according to the author, this is a mixture of tribromohydroxydiketodihydropentene and unaltered bromanilic acid.

Tetrachlorotetraketohexamethylene is also decomposed by water, forming the corresponding trichlorhydroxydiketodihydropentene. As an intermediate product, tetrachlorhydroxydiketopentamethylenecarboxylic acid is probably formed, but could not be isolated; the author doubts, therefore, whether the stable compound described by Hantzsch under that name (this vol., p. 131) has, in reality, the constitution assigned to it.

These results show that there is no necessity for assuming tautomerism in the chloranilic acids, as in its salts the metal is in no case directly combined with a carbon-atom.

When quinone is treated with 1 mol. of bromine in chloroform solution, it is converted into *quinone dibromide*, $C_6H_4O_2Br_2$. This crystallises in flat, yellow needles, which have a greenish surface lustre, and melt at 86°. It has a slight quinone-like odour, and is converted by boiling water into monobromoquinone, and on treatment with zinc-dust and acetic acid, again forms quinone. This compound was obtained nine years ago by Sarauw (Abstr., 1881, 1135), who, however, on account of its somewhat peculiar behaviour, regarded it as an isomeric dibromoquinol.

If to a chloroform solution of quinone, 2 mols. of bromine be added, *quinone tetrabromide*, $C_6H_4O_2Br_4$, is obtained. This is a colourless and odourless compound, which is very sparingly soluble in all ordinary solvents, becomes yellow at 110°, and evolves hydrogen bromide rapidly at 170—175°. On boiling with aqueous alcohol, it is converted into a mixture of equal parts of meta- and para-dibromoquinone. On reduction with zinc-dust and acetic acid, it is also reconverted into quinone.

The formation of a dibromide and tetrabromide follows naturally from Fittig's formula for quinone,  $CO<\begin{smallmatrix}CH:CH\\CH:CH\end{smallmatrix}>CO$, but not from the peroxide formula. Their formation can also be explained by Claus' diagonal formula, , but if this were correct, the anilic acids, such as chloranilic acid, the formula of which would then be , should readily pass into derivatives of diquinoyl, , whereas, all attempts to effect this change have been without success. H. G. C.

Stereochemically Isomeric Oximes of Paratolyl Phenyl Ketone. By A. Hantzsch (*Ber.*, 23, 2325—2332).—Auwers (this vol., p. 503) was able to obtain but one oxime of paratolyl phenyl ketone, $OH\cdot N:CPh\cdot C_6H_4Me$. The author finds that the product obtained by his methods is in each case a mixture of two isomeric oximes which can be isolated by dissolving the mixture in acetic acid, and fractionally precipitating them by the careful addition of water. That which comes down first melts at 154°, and is termed the α-variety. The β-isomeride melts at 115—116°, and is much more soluble in all solvents except water. Raoult's method shows that both have the formula $C_{14}H_{13}NO$, so that this is a case of true isomerism, and not of polymerism. The β- cannot be converted into the α-variety, but it is remarkable that the α-variety is converted into the β- (of lower melting point) when it is heated at 140° with hydroxylamine hydrochloride in alcohol and water. When treated with benzyl chloride and sodium ethoxide in alcoholic solution, the two varieties behave differently. The α-oxime yields a benzyl-derivative, $C_6H_4Me\cdot CPh:N\cdot O\cdot CH_2Ph$, crystallising from alcohol in well-formed, long, brilliant prisms, which melt at 85°, and dissolve very easily in ether and very sparingly in alcohol. The β-oxime yields, although less easily, a stereochemical isomeride, which separates from alcohol as an oil that very slowly solidifies in spherical aggregates of small needles. It melts at 45—47°, and is only sparingly soluble in alcohol. It is easily convertible into the α-isomeride melting at 85°; for example, by dissolving it in ether and passing hydrogen chloride into the solution.

We have thus two series of derivatives of stereochemically isomeric paratolyl phenyl ketones:  $\begin{matrix}Ph\cdot C\cdot C_6H_4Me\\ \|\\ N\cdot OH\end{matrix}$ and  $\begin{matrix}Ph\cdot C\cdot C_6H_4Me\\ \|\\ HO\cdot N\end{matrix}$, with the following melting points:—

	Oximes.	Benzyl-derivative of oximes.
α	154°	85°
β	115—116°	45—47°

C. F. B.

Formation of Racemic Acid by the Oxidation of Unsaturated Acids. By O. DOEBNER (*Ber.*, 23, 2372—2377; compare this vol., pp. 176, 1007).—The author has previously prepared 2′ : 4′-dicarboxylic acids of the quinoline series by the oxidation of 2′ : 4′-cinnamenylquinolinecarboxylic acids; the disruption of the molecule takes place at the position of the double bond in the cinnamenyl-group, $C_6H_5{\cdot}CH{:}CH$. If this reaction were a general one, certain other unsaturated acids containing the same group should yield fumaric or maleïc acids, which, in the presence of potassium permanganate, would be converted into racemic and mesotartaric acids respectively.

Cinnamenylacrylic acid, $CHPh{:}CH{\cdot}CH{:}CH{\cdot}COOH$ (10 grams), is neutralised with potassium hydroxide, and the solution, diluted to 2 litres, is cooled to 2—3°, and a solution of potassium permanganate (15 grams) in water (2 litres) at the same temperature is gradually added; the solution smells strongly of benzaldehyde; it is allowed to remain for two or three hours, and is then filtered, and concentrated to about one-sixteenth its bulk; on adding hydrochloric acid to the solution, a considerable evolution of carbonic anhydride takes place, and benzoic acid is precipitated; this is separated, and the filtrate treated with excess of ammonia and calcium chloride. The insoluble mixture of calcium salts thus obtained is now dissolved in hydrochloric acid, diluted, boiled, and treated, first with excess of ammonia, and then with excess of acetic acid, the solution is quickly filtered, and on cooling calcium racemate crystallises out; from this the free acid and various other salts were prepared. No trace of mesotartaric acid could be detected. Piperic acid, oxidised in the same manner, yields piperonal and piperonylic acid, together with carbonic anhydride, racemic and oxalic acids. This result is an additional proof of the correctness of the formula

$$CH_2{<}\begin{smallmatrix}O\\O\end{smallmatrix}{>}C_6H_3{\cdot}CH{:}CH{\cdot}CH{:}CH{\cdot}COOH,$$

for piperic acid. Acetaldehyde, carbonic anhydride, oxalic and racemic acids are obtained from sorbic acid, which should, therefore, probably be represented by the formula $CHMe{:}CH{\cdot}CH{:}CH{\cdot}COOH$.

No fumaric acid was observed in any of these experiments, so that the question of its formation as an intermediate product remains an open one. J. B. T.

Stereochemically Isomeric Oximes of Phenyl Thienyl Ketone and Phenylglyoxylic Acid. By A. HANTZSCH (*Ber.*, 23, 2332—2333).—Phenyl thienyl ketoxime, $OH{\cdot}N{:}CPh{\cdot}C_4H_3S$, exists in two isomeric modifications, a more soluble, melting at 91—92°, and a less soluble, melting at 113—114°.

The oxime of phenylglyoxylic acid, $OH{\cdot}N{:}CPh{\cdot}COOH$, exists in a less soluble stable form, melting at 145°, and in a more soluble unstable form, melting at 125°, which can be converted directly into the other variety. C. F. B.

Gallic Acid, Tannin, and Oak-tannin. By C. BÖTTINGER (*Annalen*, **258**, 252—260).—When sodium is gradually added to an alcoholic solution of anhydrous gallic acid, a blue colour is produced where the metal comes in contact with the liquid, but the colour soon disappears again, and a basic salt of gallic acid is deposited. An alcoholic solution of tannin, under the same conditions, gives first a greenish-blue coloration and then a yellowish precipitate, the tannin being converted into gallic acid.

When sodium is added to a boiling amyl alcoholic solution of anhydrous tannin, the portions of the liquid in contact with the metal are coloured greenish-blue, and then a yellowish precipitate is produced, part of the tannin being converted into an amyl-derivative and part of it decomposed into gallic acid.

The acetyl-derivative of oak-tannin under the same conditions is decomposed into acetic acid, oak-tannin, and the amyl-derivative of the last-named compound. In ethyl acetate solution, tannin and tannin-derivatives of this ethereal salt are formed, together with small quantities of gallic acid. F. S. K.

Constitution of Benzene. Reduction-products of Phthalic Acid. By A. v. BAEYER (*Annalen*, **258**, 145—219; compare this vol., pp. 875 and 1130, and Abstr., 1889, 1176).—Phthalic acid, on reduction with sodium amalgam, gives various hydrophthalic acids which, just as is the case with the hydroterephthalic acids, behave like unsaturated compounds of the fatty series; the theory of both classes of compounds must, therefore, be based on the same principles.

As the author has recently (*Ber.*, **23**, 1272) had an opportunity of stating his present views, the constitution of benzene is not discussed in this paper, except in so far that he replies to the criticisms of Ladenburg (this vol., p. 881), and gives an explanation, omitted from the address delivered at the Kekulé festival, of the changes which take place in the process of substitution.

According to Kekulé, the formation of a substitution-product, such as bromobenzene, is preceded by the formation of an additive compound (benzene dibromide), from which the final product is formed by the elimination of hydrogen bromide, the double linking being at the same time regenerated. Since the simultaneous formation of both an ortho- and a para-compound in processes of this nature could not be explained in accordance with Kekulé's benzene formula, which, moreover, did not account for the complete symmetry (formation of only one ortho-compound) of the true benzene-derivatives, other formulæ, namely, those of Claus and Armstrong, were suggested: formulæ which would explain all substitution phenomena.

Kekulé's view has, however, now been proved to be correct experimentally; terephthalic acid, on reduction, yields a paradihydro-additive product, $\Delta^{2\,5}$ dihydroterephthalic acid, the ethyl salt of which is reconverted into ethyl terephthalate on exposure to the air (compare Baeyer and Herb, this vol., p. 1130). The recent study of the behaviour of muconic acid on reduction (compare Baeyer and Rupe, *ibid.*, p. 875) has also shown that Kekulé's formula, which before this time afforded an explanation of the formation of ortho-additive products only, can now account for the formation of para-additive compounds, and, consequently, also of para-eliminations.

After replying to some remarks of Claus (Abstr., 1889, 1061), and elaborating at some length the theory of the hydroterephthalic acids, the author proceeds to discuss the constitution of the hydrophthalic acids described below.

It will be proved beyond all doubt that the hexahydrophthalic acids contain the two carboxyl-groups in the ortho-position; this must, therefore, also be true as regards the tetra- and di-hydro-acids, which bear the same relation to the hexahydro-compounds as an unsaturated does to a saturated fatty acid.

According to the theory advanced in the case of the hydroterephthalic acids there may exist, exclusive of enantiomorphous forms, 11 position-isomeric and 4 geometrically isomeric hydrophthalic acids; 7 of these isomerides, namely, 1 dihydro-, 4 tetrahydro-, and 2 hexahydro-acids have already been prepared. The system of nomenclature employed for these compounds is the same as that used for the hydroterephthalic acids (Abstr., 1889, 1176), the formula of the hexahydro-acid,  numbered as shown, being the one to which all the others refer.

The only dihydrophthalic acid yet known resembles the dihydroterephthalic acids in its behaviour with reagents, and is probably the $\Delta^{2:4}$ acid, but until the other isomerides have been prepared its constitution must remain undecided.

The acid described below as Δ^2 tetrahydrophthalic acid has a constitution analogous to that of Δ^1 tetrahydroterephthalic acid, which it resembles in many respects, especially in being stable towards boiling soda.

The constitution of the acids described as Δ^1, Δ^4, and Δ^3 tetrahydrophthalic acid respectively is discussed below; it may, however, be here remarked that the conversion of the Δ^1 into the Δ^2 acid by hot potash is a change analogous to the conversion of citraconic into itaconic acid by boiling water, as may be seen by studying the constitutional formulæ of the four compounds. A comparison of their properties and behaviour shows the relationship between the Δ^1 acid and citraconic acid on the one hand, and the Δ^2 acid and itaconic acid on the other, still more plainly, and affords further evidence that the double binding in the aromatic acids is really in the Δ^1 and Δ^2 position respectively.

On comparing the properties of the hexahydrophthalic acids described below with those of the hexahydroterephthalic acids, it will be seen that in both cases the more sparingly soluble and higher-melting compound is stable towards hydrochloric acid, whereas the more readily soluble and lower-melting acid undergoes intramolecular change into the other form when treated with the halogen acid; this is also true in the case of hexahydro- and isohexahydromellitic acids. The more readily soluble modification of hexahydroterephthalic acid has been previously compared with maleic acid, and the more sparingly soluble with fumaric acid, but no proof has yet been given that the two carboxy-groups in the unstable form are really situated on the same side of the ring; that this is so as regards the unstable form of hexahydrophthalic acid can, however, be shown, but it is necessary first to prove that the two carboxy-groups are in the ortho-position.

The proof that the carboxy-groups of hexahydrophthalic acid are in the ortho-position is afforded by the fact that the acid is obtained by reducing the Δ^1 tetrahydro-acid, which from its resemblance to dimethylmaleic acid (pyrocinchonic acid) and methylmaleic acid (citraconic acid), and from its giving adipic acid on oxidation, must contain ortho-carboxyl-groups. Further, since only one hexahydrophthalic acid yields an anhydride (hexahydroisophthalic acid and hexahydroterephthalic acid do not), this particular one must contain the two carboxy-groups in the ortho-position; the complete analogy in the behaviour of hexahydrophthalic acid and dimethylsuccinic acid also shows that the former is an ortho-derivative.

The fact that the carboxyl-groups in hexahydrophthalic acid are in the ortho-position is a new proof of the incorrectness of the prism formula, in accordance with which they should be in the meta- or para-position.

Now, if the constitution of the two hexahydrophthalic acids is studied with the aid of Kekulé's atom-models, it will be seen that in one case the two carboxyl-groups are on the same side (maleïnoid form), in the other on different sides (fumaroïd form) of the ring. Assuming that the readily soluble unstable acid is represented by the maleïnoïd formula, it should give an anhydride more readily than the isomeride; experiment has shown that this is the case. According to Wislicenus' hypothesis, the fumaroid acid should not form an anhydride, but, as it does so, it must follow that, owing to greater "spannung," this anhydride will be less stable than that of the maleïnoid acid, as will be seen by studying the molecule-models of the two compounds; this conclusion is also in accordance with observed facts, as, on heating, the fumaroid is converted into the maleïnoid form.

These arguments show that the more sparingly soluble hexahydrophthalic acid is the fumaroïd, and the readily soluble acid the maleïnoïd modification.

The explanation of the difference in behaviour between fumaric acid and the fumaroïd hexahydrophthalic acid, as regards anhydride formation, is given by an examination of the molecule-models of the two compounds.

According to Van't Hoff's theory, hexahydrophthalic acid may exist in an active and in an inactive modification, as it contains two asymmetric carbon-atoms; a consideration of the constitutional formulæ of the two acids will show that the maleïnoïd is the optically inactive modification, whilst the fumaroïd acid, although actually inactive is, just like racemic acid, composed of two active modifications, which, however, have not yet been separated from one another.

Dihydrophthalic acid cannot be obtained by the method previously described by Baeyer (Abstr., 1887, 370), as a mixture of isomeric tetrahydro-acids and a variable quantity of a hexahydro-acid is formed under these conditions. On reducing phthalic acid with sodium amalgam in cold sodium carbonate solution exactly as described by Graebe and Born (*Annalen*, **142**, 330), a mixture of dihydro- and tetrahydro-acids is produced; when phthalic acid is suspended in water, and treated with sodium amalgam, it is very quickly reduced, but phthalide and other compounds are formed.

Dihydrophthalic acid, $C_8H_8O_4$, can, however, be prepared by dissolving phthalic anhydride (60 grams) and crystalline sodium carbonate (120 grams) in water (420 grams) at the ordinary temperature, and adding 3 per cent. sodium amalgam (250 grams); as soon as the whole of the amalgam is decomposed, the solution is saturated with carbonic anhydride, and a further quantity (250 grams) of amalgam added, the process being repeated until 1500 grams have been employed. In about five days' time reduction is complete, the reaction being at an end when the lead salt of the acid obtained is readily soluble in 50 per cent. acetic acid. The decanted solution is slightly acidified with dilute hydrochloric acid, filtered, mixed with excess of dilute sulphuric acid, the precipitated acid separated by filtration, and recrystallised from hot water; the yield of the pure product is about 85 per cent. of the anhydride employed. It separates from water in well-defined, asymmetric crystals, melts at 215° when quickly heated, and is readily soluble (1 in 16) in boiling, but only sparingly (1 in 208) in cold water; its solution in sodium carbonate quickly decolorises potassium permanganate. The normal alkaline salts cannot easily be obtained, as, when a neutral solution is evaporated over sulphuric acid, crystals of the acid salt are deposited; the *potassium hydrogen* salt and the *sodium hydrogen* salt crystallise in plates. The *barium* salt is more readily soluble in hot than in cold water; the *barium hydrogen* salt crystallises in plates, and is more sparingly soluble than the normal salt. The *calcium* salt crystallises in needles, and is sparingly soluble, the *calcium hydrogen* salt in colourless plates, and is readily soluble in water. The *methyl* salt, $C_6H_6(COOMe)_2$, prepared by passing hydrogen chloride into a methyl alcoholic solution of the acid, boils at about 250°. When the acid is warmed with phosphoric chloride, it is converted into phthalic anhydride. It will be seen from the above that the description of this dihydro-acid and its salts given by Graebe and Born (*loc. cit.*) is not quite accurate in some respects.

Dihydrophthalic acid dihydrobromide, $C_8H_{10}Br_2O_4$, is obtained when the dihydro-acid is heated at 100° for 10 hours with an aqueous solution of hydrogen bromide saturated at 0°. It separates from dilute hydrobromic acid in plates melting at 215°, and from water in crystals melting at 200°, which contain 1 mol. H_2O; it is moderately stable towards potassium permanganate, and is converted into hexahydrophthalic acid on reduction with zinc and acetic acid, a fact which proves that the two bromine-atoms are not in the ortho-position to one another.

Dihydrophthalic acid dibromide, $C_8H_8Br_2O_4$, is formed when the acid is exposed to the vapour of bromine in the dark, and the yellowish product washed with sulphurous acid. It separates from hot dilute alcohol in crystals, melts at 185°, and decomposes on prolonged heating at 100°; it is oxidised by potassium permanganate, but not so quickly as dihydrophthalic acid, into which it is converted on reduction with zinc-dust and acetic acid. The *methyl* salt, prepared by brominating methyl dihydrophthalate, crystallises from methyl alcohol in prisms, and melts at 119°.

All attempts to convert dihydrophthalic acid into isomeric compounds were unsuccessful; it is very stable, and is only slowly acted on by alkalis and acids. It is the only reduction-product of phthalic acid which does not give an anhydride when treated with acetic chloride; it dissolves freely in warm acetic chloride, and on evaporating the solution there remains a colourless, gum-like mass which is completely soluble in sodium carbonate; when heated alone it is converted into phthalic anhydride and benzoic acid, but when warmed with phosphorus oxychloride, it yields an anhydride melting at about 120°, the constitution of which has not yet been determined.

Δ^2 *Tetrahydrophthalic acid* is formed, together with small quantities of the Δ^4 tetrahydro-acid, when phthalic anhydride (5 grams) and crystalline sodium carbonate (10 grams) are dissolved in water (35 c.c.), 3 per cent. sodium amalgam added, and the mixture boiled until the amalgam is completely decomposed; the solution is then slightly acidified with hydrochloric acid, filtered after some time, mixed with excess of dilute sulphuric acid, the precipitated acid separated by filtration, and washed with the least possible quantity of water. The Δ^2 tetrahydro-acid can also be obtained by reducing the dihydro-acid described above in like manner (compare Abstr., 1887, 370), but a larger quantity of the Δ^4 tetrahydro-compound is produced than in the reduction of phthalic acid. The dry, finely-divided crude product is treated with acetic chloride ($3\frac{1}{2}$ parts), the mixture kept for 1—2 days at the ordinary temperature, and the insoluble Δ^4 acid separated by filtration; the solution of the Δ^2 anhydride is evaporated, moisture being excluded, the residue dissolved in ether, and the solution shaken with concentrated potassium carbonate, until it ceases to colour the alkali yellow, in order to free it from traces of the dihydro-acid; the filtered ethereal solution is then evaporated, and the residue recrystallised from water. The Δ^2 acid thus prepared still contains small quantities of a more readily soluble acid, from which it can be separated either by recrystallisation from water, or by fractional precipitation from its alkaline solution, the pure tetrahydro-acid being deposited first in well-defined crystals. It melts at 215° when quickly heated, and is sparingly soluble (1 in 114 at 10°) in water; it combines with bromine (vapour), yielding a saturated *bromide* melting at about 225°. The *methyl* salt is a colourless oil, which forms with bromine a crystalline bromide melting at 73—74°, and also an oily compound.

Δ^2 Tetrahydrophthalic acid is very stable, and is not changed by boiling concentrated alkalis; on oxidation with potassium permanganate in sodium carbonate solution, it seems to yield a more complex acid, which is then decomposed into succinic acid, smaller quantities of oxalic acid, and an acid which may possibly be glutaric acid. The *anhydride*, prepared as described above, crystallises from ether in prisms, melts at 78—79°, and is reconverted into the acid by hot water. When the acid is heated at its melting point, it is converted into the anhydride, but at the same time the anhydride of the Δ^1 tetrahydro-acid is formed.

Δ^1 *Tetrahydrophthalic acid* is most conveniently obtained by heating the Δ^2 tetrahydro-acid (50 grams), prepared as described above, for about half an hour at 220—230° in a small retort, until water ceases to be eliminated; the brown, crystalline powder is then dissolved in hot water, and the solution evaporated on the water-bath in a tared dish until the weight of the residue is 42 grams. In this way the Δ^1 tetrahydro-acid can be separated from all the other acids, as it alone is converted into its anhydride at 100°. The anhydride is then dissolved in ether, the solution shaken with concentrated potassium carbonate, filtered, and partially evaporated; the crystalline product which is deposited on cooling is extracted with cold light petroleum, the extract evaporated, and the residual anhydride recrystallised from ether. It forms large plates, melts at 74°, and is insoluble in cold, but soluble in hot, water, being thereby converted into the acid; it is readily volatile at 100°, a property which can be made use of to test its purity.

Δ^1 Tetrahydrophthalic acid is very readily soluble in water, from which it separates slowly in large, well-defined, monosymmetric, efflorescent crystals containing 1 mol. H_2O; the damp, crystalline substance melts at a temperature below 100°, being converted into the anhydride, but the dry acid melts at 120°, also with elimination of water. It is identical with the tetrahydrophthalic acid (m. p. 96—100°) obtained by the slow distillation of hydromellitic acid (*Annalen*, **166**, 346); when hydromellitic acid is heated quickly, in small quantities at a time, it gives an oily anhydride, which is probably identical with the anhydride of Δ^1 tetrahydrophthalic acid.

The anhydride of the Δ^1 tetrahydro-acid resembles symmetrical dimethylmaleïc anhydride, not only in appearance, but also in being easily formed from the acid; both anhydrides show, moreover, a great similarity in their behaviour with reagents, and both are volatile at 100°. Concentrated hydrobromic acid at 100° and bromine in the cold have no action on either of the two compounds, although the anhydride of the Δ^1 acid is acted on by bromine at 100°, substitution, and not simple addition, takes place. The acids themselves also show a similar behaviour; pyrocinchonic acid is reduced to dimethylsuccinic acid by sodium amalgam at 100°, Δ^1 tetrahydrophthalic acid being converted into the hexahydro-acid under the same conditions. The methyl salts of both acids combine very readily with bromine. The great resemblance between these two acids and their derivatives, and the great stability of tartrophthalic acid (*Annalen*, **166**, 358), are facts which show that the Δ^1 tetrahydro-acid has doubtless the constitution assigned to it above; this view is confirmed by its behaviour on oxidation. Δ^1 Tetrahydrophthalic acid in sodium carbonate solution is oxidised to adipic acid by 3 per cent. potassium permanganate, but it is much more slowly acted on than any other hydrophthalic or hydroterephthalic acid, because it does not contain a tertiary hydrogen-atom; it is also less readily oxidised than dimethylmaleïc acid, because an "internal pressure" (compare *Ber.*, **23**, 1281) strengthens the double binding. It undergoes intramolecular change under the influence of potash at a high temperature, being converted into the Δ^2 tetrahydro-acid, but it is not changed when boiled with very concentrated soda, owing to the insolubility of the sodium salt.

Methyl Δ^1 *tetrahydrophthalate*, prepared by passing hydrogen chloride into a methyl alcoholic solution of the Δ^1 anhydride, is an oil, and combines readily with bromine in ethereal solution, yielding a crystalline substance which consists of two *dibromides*, one of which is readily soluble in cold light petroleum, and crystallises therefrom in plates melting at 83—84°, the other crystallising from a mixture of ether and light petroleum in needles melting at 123—124°. These two compounds are doubtless substitution-products of the maleïnoid and fumaroid acids; on reduction with zinc-dust and acetic acid, they both yield methyl Δ^1 tetrahydrophthalate. The *dibromide* of the acid cannot be formed directly, but it can be obtained by hydrolysing the dibromide of the methyl salt with hydrobromic acid at 100°; it is a crystalline powder sparingly soluble in water, and on reduction, it is converted into the Δ^1 tetrahydro-acid.

$\Delta^{4\ \text{cistrans}}$ *Tetrahydrophthalic acid* is best prepared by treating the crude product, obtained by the reduction of the dihydro-acid with sodium amalgam, with acetic chloride, as described in the purification of the Δ^2 acid, and after washing the residue with ether, crystallising it from water, in which it is very sparingly soluble. It crystallises in plates, melts at 215—218°, and resembles the fumaroid hexahydrophthalic acid very closely, from which it can be distinguished by the fact that it decolorises potassium permanganate momentarily; when exposed to the vapour of bromine, it gives a saturated bromide. The *methyl* salt melts at 39—40°, and yields a *dibromide* which crystallises from methyl alcohol in plates melting at 116—117°. The *anhydride* is obtained when the acid is boiled for a long time with acetic chloride; it crystallises from ether in needles and melts at 140°.

The very complete resemblance in physical properties between the Δ^1 tetrahydro-acid and its anhydride with the fumaroïd hexahydro-acid and its anhydride renders it highly probable that both acids contain the group $\text{COOH}\cdot\overset{|}{\text{C}}\text{H}\cdot\overset{|}{\text{C}}\text{H}\cdot\text{COOH}$, from which it follows that the tetrahydro-compound must be either a Δ^3 or a Δ^4 derivative. But since, judging from the behaviour of the analogously constituted Δ^2 tetrahydroterephthalic acid, the Δ^1 tetrahydrophthalic acid should undergo intramolecular change on boiling with soda, the fact that the acid described as Δ^4 tetrahydrophthalic acid is stable under these conditions is evidence that it has the constitution assigned to it.

Δ^3 *Tetrahydrophthalic acid* is deposited in needles when the anhydride of the Δ^4 acid is heated for 2½ hours at 210—220°, the oily product extracted with boiling water, and the solution concentrated by evaporation. It melts at 174°, is readily soluble in water, and is distinguished from all other hydrophthalic acids yet prepared by its instability towards soda; when boiled therewith for a short time, it is converted into a sparingly soluble, crystalline acid melting at 208°, which consists of a mixture of the Δ^2 and Δ^4 tetrahydro-acids; these two compounds can be separated by treating the finely-divided mixture with acetic chloride. As, further, the Δ^2 acid on heating is partially converted into the Δ^1 anhydride, the double binding can be shifted successively from the Δ^4 to the Δ^3, Δ^2, and Δ^1 position.

The author explains the formation of Δ^3 tetrahydrophthalic acid from the Δ^4 compound by assuming that, on heating the fumaroïd Δ^4 anhydride, it is not only converted into the maleïnoïd modification, but that the double binding shifts from the Δ^4 to the Δ^3 position; arguing from the behaviour of fumaroïd hexahydrophthalic acid, the product should be the maleïnoïd Δ^4 acid, but the fact that it readily undergoes intramolecular change when treated with soda renders it improbable, judging by previous experience, that it is simply the maleïnoïd form of the stable fumaroïd acid, so that it has most probably the constitution assigned to it.

Fumaroïd hexahydrophthalic acid, $C_8H_{12}O_4$, has been previously prepared (*Ber.*, **4**, 276) by reducing the Δ^1 tetrahydro-acid obtained by the distillation of hydropyromellitic acid. It can also be obtained by reducing the dihydrobromide of the dihydro-acid, but it is best prepared by reducing the hydrobromide of crude tetrahydrophthalic acid with sodium amalgam in ice-cold sodium carbonate solution; the product is purified by treating it with a solution of potassium permanganate at the ordinary temperature until the coloration remains permanent for 15 minutes. It crystallises from water in plates very like the crystals of hexahydroterephthalic acid in appearance, and it separates from acetone in long, monosymmetric needles; it is more sparingly soluble in water (1 in 434 at 20°) than any of the other hydrophthalic acids yet prepared. It begins to melt at 215° when quickly heated, and is completely liquefied at 221°. Taking the melting point to be 215°, the following four acids, namely, fumaroïd hexahydro-, Δ^2 and fumaroïd Δ^4 tetrahydro-, and dihydro-phthalic acid have the same melting point. It distils unchanged when quickly heated, but on prolonged heating at a temperature above its melting point, water is eliminated, and it is partially converted into the anhydride of the maleïnoïd acid; its solution in hot sodium carbonate gradually decolorises potassium permanganate, but no action takes place in the cold. The calcium salt is characterised by being very sparingly soluble. The *methyl* salt, $C_8H_{10}O_4Me_2$, melts at 33°, and is moderately easily soluble in light petroleum. The *anhydride*, $C_8H_{10}O_3$, prepared by warming the acid with acetic chloride, crystallises from ether in long needles and melts at 140°. When the acid is warmed with bromine (2 mols.) and phosphoric chloride for six hours, it is converted into a syrup which, on reduction with zinc-dust and acetic acid, yields a sparingly soluble acid resembling the Δ^2 tetrahydro-acid, and some readily soluble products, but the Δ^1 tetrahydro-acid is not obtained. The anhydride shows a like behaviour.

Maleïnoïd hexahydrophthalic acid is obtained when the anhydride of the fumaroïd acid is heated for seven to eight hours at 210—220°, the product dissolved in water, the solution evaporated to dryness, and the residual acid treated with potassium permanganate in alkaline solution until a permanent coloration is produced. It crystallises from water, in which it is more readily soluble than the isomeride, in four-sided prisms, sinters together at about 182°, and melts at 192°. It behaves like the fumaroid acid with potassium permanganate, and when heated with concentrated hydrochloric acid at 180°, it is reconverted into the fumaroid modification. The barium salt and the zinc salt are more sparingly soluble in hot than in cold water. The *anhydride* is formed when the acid is heated to its melting point; it boils at 145° (18 mm.) and melts at 32°.

When Δ^1 tetrahydrophthalic acid is reduced with sodium amalgam, a mixture (m. p. 183°) of the two hexahydro-acids is obtained, but the two compounds cannot easily be separated by recrystallisation from water. This fact explains why the hexahydro-acid obtained by the reduction of the Δ^1 tetrahydro-acid with sodium amalgam is quite different in appearance from that obtained by reducing the same compound with hydriodic acid (compare *Annalen*, **166**, 350).

F. S. K.

The Constitution of Benzene. By A. CLAUS (*J. pr. Chem.* [2], **42**, 260—267).—A reply to Baeyer's last publication on the same subject (preceding abstract), and chiefly of a personal nature.

H. G. C.

Symmetrical Alkylisophthalic Acids. By O. DOEBNER (*Ber.*, **23**, 2377—2381).—The formation of uvitic acid from pyruvic acid is due to the decomposition of part of the pyruvic acid into acetaldehyde and carbonic anhydride, and to the subsequent condensation of the aldehyde with the remaining acid. If some other aldehyde is employed, corresponding homologues of uvitic acid are obtained; the reaction probably takes place in two stages:—$3COMe{\cdot}COOH +$

$R{\cdot}CHO = RC{<}{\substack{CH{:}C(COOH)\\ CH{\cdot}C(COOH)}}{>}C{\cdot}CO{\cdot}COOH + 3H_2O + H_2$; by the action of barium hydroxide on this hypothetical intermediate product, oxalic acid is eliminated, and the symmetrical acid

$$C_6H_3R{\cdot}(COOH)_2$$

is produced.

Ethylisophthalic acid, $C_6H_3Et(COOH)_2$, is prepared by boiling crystallised barium hydroxide (120 grams) with pyruvic acid (50 grams) and propaldehyde (16 grams) for eight hours in a reflux apparatus; the product is filtered whilst hot, and the residue boiled out several times with water; the combined filtrates are then evaporated, and excess of hydrochloric acid added; the precipitate, when treated with hot water and crystallised from dilute alcohol, forms colourless plates which melt at 263—264°, and at higher temperatures sublime with partial decomposition. It is readily soluble in alcohol, ether, benzene, and glacial acetic acid, but very sparingly in water, and is insoluble in light petroleum. The salts of the *alkali metals* and the *calcium*, *barium*, and *magnesium salts* readily dissolve in water; the *lead*, *copper*, and *silver salts* are less soluble. The calcium salt yields ethylbenzene on heating.

Isopropylisophthalic acid, $C_6H_3Pr^\beta(COOH)_2$, is formed from isobutaldehyde and pyruvic acid in a manner similar to the ethyl-derivative, which it closely resembles; it crystallises from dilute alcohol or acetic acid in colourless plates melting at 275—276°.

Isobutylisophthalic acid, $C_4H_9 \cdot C_6H_3(COOH)_2$, is obtained from isovaleraldehyde; it crystallises in colourless, lustrous plates which melt at 260°.

Phenylisophthalic acid, $C_6H_3Ph(COOH)_2$, is prepared from benzaldehyde and pyruvic acid; it is more sparingly soluble than the preceding compound, but may be crystallised from glacial acetic acid; it melts above 310°. The *barium salt* dissolves very sparingly in hot water. Diphenyl is obtained on heating the calcium salt. The constitution of the above compounds is proved by the fact that isobutylisophthalic acid yields trimesic acid on oxidation. J. B. T.

Derivatives of Phenyl Salicylate (Salol). By W. Knebel (*J. pr. Chem.* [2], **42**, 158).—*Phenyl nitrosalicylate*,

$$NO_2 \cdot C_6H_3(OH) \cdot COOPh,$$

is obtained when nitric acid is dropped into a warm solution of phenyl salicylate in glacial acetic acid; it forms lustrous needles melting at 150°, sparingly soluble in alcohol, more freely in glacial acetic acid. On hydrolysis, it yields metanitrosalicylic acid (m. p. 222°) and phenol; when heated with strong ammonia, it yields nitrosalicylamide.

Phenyl dinitrosalicylate is obtained by heating the glacial acetic acid solution of phenyl salicylate with nitric acid (sp. gr. 1·52) for some time on the water-bath; it crystallises in needles which melt at 183° and are soluble in glacial acetic acid.

Phenyl trinitrosalicylate, obtained when phenyl salicylate is added to nitric acid of sp. gr. 1·52, crystallises in silvery scales melting at 100° and easily soluble in alcohol. A. G. B.

Derivatives of Paratolylglycin. By C. A. Bischoff and A. Hausdorfer (*Ber.*, **23**, 1997—2002).—Paratolylglycin,

$$C_6H_4Me \cdot NH \cdot CH_2 \cdot COOH,$$

is readily obtained in quantity by heating chloracetic acid and paratoluidine with sodium acetate, and recrystallising the product from hot water. In an attempt to convert it into paraditolyl-$\alpha\gamma$-diketopiperazine, it was heated first at 110—120° and subsequently at 200°, the product washed with ether, recrystallised from alcohol, and boiled with ammonia to remove any unaltered glycin. The product was, however, found to be *paratolylglycinimide*, $NH(CO \cdot CH_2 \cdot NH \cdot C_6H_4Me)_2$, melting at 208—210°. It is probable that the anhydride is first formed, and that this is converted by ammonia into the imide. The latter is very stable, not being decomposed by boiling acids and alkalis. If, however, paratolylglycin is heated at 230—250° instead of the lower temperature mentioned above, it is converted into *paraditolyl-$\alpha\gamma$-diketopiperazine*, which, after recrystallisation from acetic acid, melts at 254°. By the action of acetic anhydride, paratolylglycin yields a compound melting at 219—222°, the composition of which has not yet been determined.

Paratolylphenyl-αγ-diketopiperazine,  $C_6H_4Me\cdot N{<}\begin{smallmatrix}CH_2\cdot CO\\ CO\cdot CH_2\end{smallmatrix}{>}NPh$, is obtained by heating bromacetylphenylglycin with paratoluidine and sodium acetate. It forms colourless needles melting at 220—221°, and insoluble in alkalis. An attempt was made to obtain an isomeric piperazine by the action of aniline on chloracetoparatoluidide, but the compound formed was found to be *chloroacetotoluidide*, $C_6H_4Me\cdot NH\cdot CO\cdot CH_2Cl$, which, on treatment with aniline and sodium acetate, yields *phenylglycinparatoluidide*,

$$C_6H_4Me\cdot NH\cdot COCH_2\cdot NHPh,$$

melting at 165°.

By the action of paratoluidine, chloracetic acid, and sodium acetate, *paratolylimidodiacetic acid*, $C_6H_4Me\cdot N(CH_2\cdot COOH)_2$, is formed, but decomposes so readily that it could not be obtained pure. On treatment with toluidine, it yields the *monotoluidide* melting at 222°, and a substance which is probably the impure *ditoluidide*. The first compound may also be obtained from paratolylglycintoluidide and chloracetic acid.

H. G. C.

Derivatives of Orthotolylglycin. By C. A. Bischoff and A. Hausdorfer (*Ber.*, 23, 1991—1996).—Orthotolylglycin is converted by the method previously given (Abstr., 1889, 1011) into *orthoditolyl-αγ-diketopiperazine*,  $C_6H_4Me\cdot N{<}\begin{smallmatrix}CH_2\cdot CO\\ CO\cdot CH_2\end{smallmatrix}{>}N\cdot C_6H_4Me$, the yield obtained being 63·6 per cent. Abenius and Widman were unable to obtain any piperazine in this manner. By the action of the gases evolved from arsenious oxide and nitric acid on this compound dissolved in cooled sulphuric acid, a substance is obtained, mixed with other bye-products, which does not give Liebermann's reaction, and appears to have the constitution  $NO_2\cdot C_6H_3Me\cdot N{<}\begin{smallmatrix}CH_2\cdot CO\\ CO\cdot CH_2\end{smallmatrix}{>}N\cdot C_6H_3Me\cdot NO_2$. It is purified by extraction with boiling chloroform and recrystallisation from acetic acid, and melts at 253—254°. If the sulphuric acid is not cooled, two other compounds are formed, neither of which gives Liebermann's reaction; they have the formulæ $C_{18}H_{16}N_5O_8$ and $C_{18}H_{16}N_5O_6$, and melt at 262—265° and over 300° respectively.

Orthotolylimidodiacetic acid, $C_6H_4Me\cdot N(CH_2\cdot COOH)_2$, is prepared by boiling tolylglycin (1 mol.) with chloracetic acid (1 mol.), sodium carbonate ($1\frac{1}{2}$ mols.), and a little water in a reflux apparatus. It separates from a mixture of alcohol and light petroleum in lustrous, white crystals, which melt at 158—162° with decomposition, and are insoluble in water, dilute hydrochloric acid, alkalis, and light petroleum, sparingly soluble in ether, more readily in alcohol and chloroform. On treatment with toluidine, it yields the *mono-* and *di-toluidide*, the first of which forms crystals melting at 146—148°, whilst the second melts at 149—150°. The monotoluidide, unlike the corresponding compound in the phenyl-group, does not yield a piperazine on boiling with acetic anhydride, but is converted into *diorthotolylcarbamide*, $CO(NH\cdot C_7H_7)_2$.

Phenylorthotolyl-αγ-diketopiperazine,

$\mathrm{PhN}<\genfrac{}{}{0pt}{}{\mathrm{CH_2\cdot CO}}{\mathrm{CO\cdot CH_2}}>\mathrm{N\cdot C_6H_4Me}$,

was obtained by Abenius by the action of aniline on chloracetylorthotolylglycin. It may also be obtained by heating orthotoluidine with chloracetylphenylglycin and sodium acetate. H. G. C.

Compounds of Glycuronic Acid. By E. Külz (*Zeit. Biol.*, **27**, 247—258).—*Phenylglycuronic acid*, $C_6H_{11}PhO_7$, was prepared in the following way:—Animals were dosed with phenol, and the urine, which was of a dark tint, collected and evaporated on the water-bath to a thin syrup. A mixture of 1 litre of ether, 500 c.c. of 90 per cent. alcohol, 30 c.c. of sulphuric acid (concentrated sulphuric acid and water in equal parts) was repeatedly shaken with this until no more lævorotatory substance passed into solution. The ether and alcohol were distilled off from the extract, the residue carefully neutralised with barium hydroxide, the barium sulphate filtered off, and the filtrate precipitated first with lead acetate and then with basic acetate; the precipitate produced by the latter was well washed, suspended in water, and decomposed with hydrogen sulphide, the lead sulphide filtered off, and the excess of gas driven off from the filtrate by gentle heat. On evaporation of this solution to a thin syrup, it deposited crystals of phenylglycuronic acid, which were dissolved in warm water, the solution decolorised by animal charcoal, and the crystals once more obtained on evaporation were purified by repeated recrystallisation. The crystals were long needles, resembling asbestos, burnt without residue, sublimed slowly below 100°, were charred at 100°, and melted approximately at 148°. Their solution was lævorotatory and reduced Fehling's solution. Their barium salt could not be prepared in a crystalline form, but the potassium and sodium salts crystallised from an aqueous solution. A 3 per cent. aqueous solution of the acid was distilled with sulphuric acid for three hours; it became yellow; the distillate contained phenol; the residue still reduced Fehling's solution powerfully, and was dextrorotatory; barium glycuronate was prepared from it by the method of Schmiedeberg and Meyer (*Zeit. physiol. Chem.*, **3**, 442).

The preparation of the following compounds of glycuronic acid was, *mutatis mutandis*, the same as that just described.

Quinolglycuronic acid is lævorotatory, and non-crystalline. Its barium, potassium, and sodium salts are also non-crystalline. On distillation with sulphuric acid, quinol was found in the distillate, and glycuronic acid in the residue.

Resorcinolglycuronic acid is lævorotatory, crystalline, and reduces Fehling's solution; its barium salt was also obtained in a crystalline form. On distillation with sulphuric acid, benzoic acid was found in the distillate, glycuronic acid in the residue.

Thymolglycuronic acid is lævorotatory, crystalline, and non-reducing. Its barium salt was crystallised. On distillation with sulphuric acid, very small quantities of thymol were obtained in the distillate. Thymol appears to be to a great extent decomposed by sulphuric acid, yielding an oil which smells like thymol. Glycuronic acid, as in the previous cases, was found in the residue.

Turpentineglycuronic acid has been noted in the urine of patients by previous observers. It is amorphous, lævorotatory, soluble in water and in alcohol, soluble with difficulty in ether. The barium, potassium, sodium, and silver salts are amorphous. The acid only reduces Fehling's solution after prolonged boiling. On distillation with sulphuric acid, the residue contained glycuronic acid, and the distillate, oil of turpentine. W. D. H.

So-called Anilinetrisulphonic Acid. By C. L. JACKSON and G. T. HARTSHORN (*Ber.*, 23, 2143).—The acid previously described as anilinetrisulphonic acid (Abstr., 1888, 1093) has now been found to be anilinesulphonic acid (sulphanilic acid). F. S. K.

Nitrocymenesulphonic Acids. By G. ERRERA (*Gazzetta*, 19, 533—545).—*Nitro-α-cymenesulphonic acid*, $HSO_3\cdot C_6H_2MePr\cdot NO_2$ [2 : 1 : 4 : 6]. Cymene from camphor (100 grams) is dissolved in concentrated sulphuric acid (3 vols.); on cooling, the solution separates into two layers, the lower of which is rejected; a solution of nitric acid (58 grams, sp. gr. = 1·51) in an equal volume of concentrated sulphuric acid is gradually mixed with the residue, the mass being meanwhile kept cold; it is then heated, diluted, neutralised with barium carbonate, and concentrated. Nodules of barium nitro-α-cymenesulphonate are deposited, and when recrystallised form nodules consisting of yellow or reddish needles, or thin plates containing 1 mol. H_2O, and only slightly soluble in cold water. The mother liquor eventually settles into a viscid mass. The *magnesium salt* forms white, crystalline nodules containing 5 mols. H_2O; the solutions of both barium and magnesium salts are coloured red by the light.

The acid is prepared from the barium salt; it is a heavy, brown liquid which sets into a crystalline mass when kept for some time over sulphuric acid in a vacuum, but deliquesces on exposure to the air. Both the acid and its salts deflagrate when heated to 200°, leaving a mass of spongy carbon; this occurs even in presence of water.

Nitro-α-cymenesulphonamide, $SO_2NH_2\cdot C_6H_2MePr\cdot NO_2$ [2 : 1 : 4 : 6]. —The barium salt of the preceding acid is dehydrated at 170°, heated with phosphoric chloride, and the viscid product thrown into water; the chloride of the acid radicle separates in the form of a heavy, oily liquid which combines energetically at the ordinary temperature with a saturated solution of ammonia; on cooling and recrystallising the product from dilute alcohol, the amide is obtained in micaceous scales melting at 138—139°, and readily soluble in alcohol and in hot water.

Amido-α-cymenesulphonic acid, $HSO_3\cdot C_6H_2MePr\cdot NH_2 + H_2O$ [2 : 1 : 4 : 6], is prepared by reducing nitro-α-cymenesulphonic acid with ammonium sulphide. It crystallises from boiling water in hard, brittle, brilliant, pale-yellow prisms containing 1 mol. H_2O; when its solution is rapidly cooled, it forms tables or a white powder. When heated on platinum-foil, it chars and decomposes without melting.

The salts which this acid forms with the alkalis and alkaline earths are all extremely soluble in water.

Chloro-α-cymenesulphonic acid, $HSO_3·C_6H_2MePrCl$ [2 : 1 : 4 : 6], is prepared by a modification of Sandmeyer's reaction; the powdered amido-acid is suspended in a boiling solution of cuprous chloride in hydrochloric acid, and a current of nitrous acid passed in until solution is complete. The *barium salt* forms very thin, colourless plates containing 3 mols. H_2O. *Bromo-α-cymenesulphonic acid* is obtained like the chlorinated derivative. The *barium salt* contains only 1 mol. H_2O. On heating chlorocymenesulphonic acid at 180° with fuming hydrochloric acid, and distilling the product in a current of steam, the distillate contains drops of a chlorocymene, which, on oxidation with nitric acid (sp. gr. = 1·29), yields needles of metachloroparatoluic acid, $C_6H_3MeCl·COOH$ [1 : 6 : 4], melting at 196—197°. The chlorocymene must, therefore, have the constitution [Me : Pr : Cl = 1 : 4 : 6] (Abstr., 1887, 37; 1889, 495); this, in conjunction with the circumstance that in Sandmeyer's reaction, chlorine takes the position of the amidogen, and that α-cymenesulphonic acid forms the starting point of the above compounds, establishes the constitutions ascribed to them. Amidocymenesulphonic acid is thus isomeric with Widman's cymidinesulphonic acid, $HSO_3·C_6H_2MePr·NH_2$ [2 : 1 : 4 : 5] (Abstr., 1886, 470), from which it differs in only slowly giving up its water of crystallisation even at 120—130°, whilst the latter becomes anhydrous at 110—115°; barium cymidinesulphonate, moreover, crystallises with $2\frac{1}{2}$ mols. H_2O.

It was mentioned before that the mother liquor from the barium nitro-α-cymenesulphonate congeals to a viscid mass; this mass contains barium salts too impure to crystallise. By treatment with magnesium sulphate, yellow prisms of a *magnesium* salt,

$$[C_6H_2MePr(NO_2)·SO_3]_2Mg + 6H_2O,$$

were isolated. From this a *barium* salt containing 5 mols. H_2O, and crystallising in yellow plates, was prepared. These substances are salts of an isomeric nitrocymenesulphonic acid which is now under investigation. S. B. A. A.

Formation of Acid Chlorides by the Action of Sulphonic Monochloride. By G. CARRARA (*Gazzetta*, 19, 499—504).—In view of the discordant observations of this reaction by Knapp (*Zeit. für Chem.*, 1869, 41), Armstrong (this Journal, 1871, 173), Beckurts and Otto (Abstr., 1879, 229), Spica (Abstr., 1881, 602), Paternò and Canzoneri (Abstr., 1881, 593), and by the author, the action of sulphonic monochloride on chlorocymene was investigated. Amounts corresponding respectively with 1 and 2 mols. of the former to 1 mol. of the latter were maintained at 98—100° until the evolution of hydrogen chloride had almost ceased, the product treated with excess of hot water, washed, and dried at 100°. In both experiments, the product consists of chlorocymenesulphonic chloride, $C_{10}H_{12}Cl·SO_2Cl$, but the yield from the double proportion of sulphonic chloride is more than five times as great as that from the single quantity. This difference is attributed to a secondary action of sulphonic chloride on the chlorocymenesulphonic acid first formed. To confirm this view, the acid was directly treated with sulphonic chloride, and a yield of 56 per cent. of the acid chloride obtained. The equation $C_{10}H_{12}Cl{\cdot}SO_2{\cdot}OH + SO_2Cl{\cdot}OH = C_{10}H_{12}Cl,SO_2Cl + H_2SO_4$ therefore affords a more probable representation of the formation of the acid chlorides than that given by Beckurts and Otto (*loc. cit.*). The author confirms Paternò and Canzoneri's observation that bromocymenesulphonic chloride is not affected by the action of water, but is converted into the sulphonic acid by boiling with alcohol. It is found, however, that if the solutions of acid chloride and alcohol are only heated together for 1½ hours, and allowed to evaporate spontaneously, a deposit of white, pointed, prismatic crystals of an *ethyl salt*, $C_{10}H_{12}Cl,SO_3Et$, forms after a few days. The crystals melt at 42—43°, and, unlike the sulphonic acid, only dissolve very partially in water after prolonged boiling, a portion passing over with the steam: they dissolve in ether and benzene, and volatilise with decomposition at about 110—120°. The presence of this intermediate compound explains the conversion of the acid chloride into the sulphonic acid, which, probably, takes place in two stages as follows:—

(1.) $C_{10}H_{12}Cl{\cdot}SO_2Cl + EtOH = C_{10}H_{12}Cl{\cdot}SO_3Et + HCl$
(2.) $C_{10}H_{12}Cl{\cdot}SO_3Et + H_2O = C_{10}H_{12}Cl{\cdot}SO_3H + EtOH.$

S. B. A. A.

Dibenzamide. By F. KRAFFT (*Ber.*, 23, 2389—2393).—Dibenzamide is prepared by treating benzoic chloride (16 grams) with benzonitrile (30 grams) and aluminium chloride (16 grams) for some time at 100°; the solid product is treated first with water, then with dilute alcohol, and finally with dilute sodium hydroxide solution; the insoluble residue consists of kyaphenine. On adding excess of hydrochloric acid to the alkaline filtrate, a precipitate is formed, which is purified by dissolving in warm alcohol and adding water; the yield is fairly large. Dibenzamide crystallises in lustrous needles melting at 147—148°; on distillation, even under reduced pressure, it decomposes into benzonitrile and benzoic acid.

Benzoic acid and benzamide are produced by boiling dibenzamide for a day with a large excess of water. Dilute acids act in the same way, only more rapidly. Dibenzamide readily dissolves in cold dilute sodium hydroxide solution, and is precipitated unchanged by the immediate addition of hydrochloric acid; but if the alkaline solution is allowed to remain for some time, benzamide and sodium benzoate are formed (compare Bath and Senhofer, Abstr., 1876, 417).

Sodium dibenzamide may be prepared by digesting dibenzamide with sodium wire in anhydrous ether for 1—2 days. *Silver dibenzamide*, $NAgBz_2$, is obtained as a flocculent, crystalline precipitate on adding a cold, aqueous solution of silver nitrate to an ammoniacal solution of dibenzamide in alcohol. Ethyl benzoate and benzamide are formed on boiling dibenzamide with alcohol for some time.

J. B. T.

Bènzenesulphoneorthamidobenzamide and its Anhydride. By E. FRANKE (*J. pr. Chem.* [2], 42, 271—272).—Benzenesulphonoorthamidobenzamide is readily obtained by the action of benzenesulphonic chloride on orthamidobenzamide, and crystallises from benzene or hot water in white needles melting at 166°. On warming with concentrated hydrochloric acid, it yields a *hydrochloride*, $C_{13}H_{12}N_2SO_3,HCl$, crystallising in white needles. The free base readily passes into the anhydride, which crystallises from alcohol in white needles melting at 145—146°, and scarcely soluble in hot water. It also forms salts in which one atom of hydrogen is displaced by metal, and, on warming with potash and methyl iodide in alcoholic solution, yields the compound $C_{13}H_9MeN_2SO_2$, crystallising in needles which melt at 116°. H. G. C.

Diphenylacetylenediureïne and some of its Derivatives. By A. Angeli (*Gazzetta*, **19**, 563—568).—Schiff (Abstr., 1877, 885) and Franchimont and Klobbie (Abstr, 1889, 125) have examined the action of urea and ureïdes on the diketones and dialdehydes of the fatty acids; the author has now extended those experiments to some members of the aromatic group.

Diphenylacetylenediureïne, $C_{16}H_{14}O_2N_4$, is prepared by heating a mixture of benzile with 3 times its weight of carbamide at 220° for about 15 minutes. The portion of the product insoluble in hot alcohol is crystallised from glacial acetic acid. It forms a white, silky powder which does not melt at 310°. When heated on platinuum foil, it gives off white fumes and melts to a dark mass. It is insoluble in water and in benzene, but readily soluble in boiling glacial acetic acid, and slightly in hot alcohol. It dissolves in concentrated sulphuric acid, and is reprecipitated unchanged on dilution. It yields no salts, and is insoluble in alkaline liquids; with ammoniacal silver nitrate, a black precipitate is obtained consisting chiefly of reduced silver. It is formed by the condensation of 2 mols. of carbamide with 1 of benzile, and, probably, has the constitution  $CO<\begin{array}{l}NH\cdot PhC\cdot NH\\ \qquad\quad | \\ NH\cdot PhC\cdot NH\end{array}>CO$. It only forms one *acetyl-derivative*, $C_{16}H_{12}N_4O_2Ac_2$, which crystallises in spherical tufts of pale-violet needles, melting with decomposition at 266°; it is insoluble in water, and only slightly soluble in alcohol. The solutions in ethyl acetate and in acetic acid are colourless by transmitted light, but exhibit a very marked violet fluorescence; the hot alcoholic solution is decomposed by potash, with separation of the original diureïne.

When the diureïne is heated with sodium acetate and acetic anhydride for eight hours at 240°, a substance is formed having the composition $C_{15}H_{12}N_2O$. The solutions of this compound in acetic acid and in ethyl acetate likewise exhibit a violet fluorescence. It is insoluble in water and in benzene. It is probably a product of decomposition of the acetyl-derivative, and is either identical or polymeric with the compound  $CO<\begin{array}{l}NH\cdot CPh\\ \qquad \| \\ NH\cdot CPh\end{array}$. The diacetyl-derivative seems to have the constitution  $CO<\begin{array}{l}NH\cdot CPh\cdot NAc\\ \qquad | \\ NH\cdot CPh\cdot NAc\end{array}>CO$.

S. B. A. A.

Note.—The term "ureïne" is used by Franchimont and Klobbie to denote that class of ureides in which each NH-group is attached to a hydrocarbon residue and neither lies between two CO-groups; such ureïdes yield dinitro-derivatives (Abstr., 1889, 125).

Monophenylthiocarbamide and Imidothiocarbamates. By A. BERTRAM (*Inaugural Dissertation, Chem. Centr.*, 1890, i, 939—941).—*Methyl imidophenylthiocarbamate*, NHPh·C(NH)·SMe, melting at 71°, is prepared by the action of methyl iodide on monophenylthiocarbamide, as hydriodide, from which the free base is obtained by the action of sodium carbonate and extraction with ether; the hydroiodide melts at 147°. It forms two sulphates, $2C_8H_{10}N_2S,H_2SO_4$ and $C_8H_{10}N_2S,H_2SO_4$, both melting at 171°; the nitrate melts at 113°; the acetate at 115°; the picrate at 175°; the platinochloride at 184°. For the determination of the constitution of the base the following reactions were made. By means of dry distillation, it was decomposed into aniline, methyl mercaptan, and an unknown compound. Heated with carbon bisulphide at 140—150°, aniline, hydrogen thiocyanate, and phenylthiocarbimide were obtained. When heated with dilute sulphuric acid at 160°, the base yields *methyl phenylthiocarbamate*, NHPh·CO·SMe, melting at 84—85°, from which the constitution of the base is proved. With methyl iodide, the base forms an additive compound melting at 184° which, with sodium carbonate, yields a new base, *methyl imidomethylphenylthiocarbamate*, NPhMe·C(NH)·SMe. If this base is heated with dilute sulphuric acid at 160°, *methyl methylphenylthiocarbamate*, NPhMe·CO·SMe, is formed melting at 54°, which proves the constitution of the new imido-base. This base is an oil, and the picrate melts at 139°. With carbon bisulphide, it forms hydrogen thiocyanate, methyl mercaptan, phenylthiocarbimide and another substance melting at 84°. Methyl iodide reacts with methyl imidomethylphenylthiocarbamate with formation of an additive compound, the hydriodide of *methyl methylimidomethylphenylthiocarbamate*, from which the free base, NPhMe·C(NMe)·SMe, is obtained by the action of sodium carbonate. This base is an oil, the hydriodide of which melts at 184°, the picrate at 126°, and the platinochloride at 174°. Heated with carbon bisulphide at 160°, the base yields phenylthiocarbimide, and *methyl methylphenyldithiocarbamate*, NPhMe·CS·SMe, melting at 88°. With sulphuric acid, methyl methylphenylthiocarbamate is again obtained.

Methyl-symmetrical-diphenylthiocarbamide and methyl iodide combine with formation of the hydriodide of *methyl phenylimidomethylphenylthiocarbamate*, from which the free base may be obtained. With carbon bisulphide, it forms methyl methylphenyldithiocarbamate.

Ethyl iodide unites with monophenylthiocarbamide yielding the compounds corresponding with those which it forms with methyl iodide; *ethyl imidophenylthiocarbamate*, NHPh·C(NH)·SEt, is an oil; the hydriodide melts at 103°, and the picrate at 196°. Ethyl iodide combines with it, forming *ethyl imidoethylphenylthiocarbamate*, NPhEt·C(NH)·SEt; the picrate melts at 170°. If this is heated with ethyl iodide, it forms *ethyl ethylimidoethylphenylthiocarbamate*, NPhEt·C(NEt)·SEt, an oil which boils at 273° with slight decomposition; the picrate melts at 96°, the platinochloride at 135°.

Ethylene bromide reacts with monophenylthiocarbamide with formation of the compound $C_{16}H_{16}N_4S$, which is probably ethylene imidophenylthiocarbamate. The hydrobromide melts at 214°, the free base at 139°, the hydrochloride at 218°, the platinochloride at 150°, and the picrate at 196°. If the base is heated above 139°, ethylene mercaptan separates, from which it appears that the base is an imidocarbamate. If heated with carbon bisulphide, hydrogen thiocyanate, ethyl mercaptan, aniline, and an unrecognisable compound are produced.

The halogens decompose the above compounds, oxidising the thioalcohol group to the sulphonic-acid group, and convert the remainder into a dihalogen- and then into a trihalogen-carbamide, the latter yielding α-trihalogen aniline. Methyl imidophenylthiocarbamate is converted by bromine into methylsulphonic acid, tribromaniline, tribromophenylcarbamide, and dibromophenylcarbamide.

J. W. L.

Preparation of Aromatic Sulphides and of Thioxanthone. By J. H. ZIEGLER (*Ber.*, 23, 2469—2472).—By the action of diazo-compounds on sodium phenyl mercaptan, corresponding sulphides are obtained. The reaction is best carried out at a temperature of 60—70°, in order to avoid the formation of explosive diazo-derivatives. The phenyl sulphides from diazo-ortho- and para-toluene, and diazo-2-naphthalene, are viscid liquids boiling at 290—310°. *Phenyl-1-naphthyl sulphide* crystallises in plates melting at 49°. *Para-acetamidodiphenyl sulphide*, from paradiazoacetanilide, is deposited from water in white crystals melting at 144°. The free *base* is obtained by hydrolysis; it crystallises from alcohol in brownish needles melting at 97°. *Diphenylsulphideorthocarboxylic acid* is prepared by the action of alkalis on the product obtained from sodium phenyl mercaptan and diazobenzoic acid; it is deposited from benzene in white plates, which melt at 165·5°. On treatment with concentrated sulphuric acid, the compound dissolves with a very characteristic light-green fluorescence, and, on pouring into cold water, *thioxanthone* is precipitated; it is best purified by sublimation. It crystallises in almost colourless needles melting at 207°, and boiling at 371—373° under a pressure of 715 mm. It is readily soluble in benzene, glacial acetic acid, and carbon bisulphide, and is not acted on by hydroxylamine or phenylhydrazine.

J. B. T.

Methyl-derivatives of Indole. By C. ZATTI and A. FERRATINI (*Ber.*, 23, 2302—2307).—When indole or α-methylindole is heated with methyl iodide, the hydriodide of trimethyldihydroquinoline is formed, and not of dimethyldihydroquinoline as Fischer and Steche thought (Abstr., 1888, 298). When the base derived from this is heated with methyl iodide, the same trimethyldihydroquinoline hydriodide, $C_{12}H_{15}N,HI$, melting at 253°, is again obtained. At the same time, however, a more soluble salt, of the composition $C_{14}H_{19}N,HI$, is also formed, the reaction taking place according to the equation $2C_{12}H_{15}N + 2MeI = C_{12}H_{13}Me_2N,HI + C_{12}H_{15}N,HI$. Trimethyldihydroquinoline is heated for three hours at 100° in a sealed tube, with excess of methyl iodide; the contents of the tube. after evaporation of the methyl iodide, are washed with ether and separated by fractional crystallisation from alcohol into trimethyldihydroquinoline hydriodide and the penta-methyl compound, which is perhaps the methiodide compound of tetramethyldihydroquinoline. This is a pale-red, crystalline powder melting at 169°, dissolving easily in water and alcohol, but not in ether and ethyl acetate. Potash liberates the base, which is a colourless oil soluble in ether, and turning red in the air. It dissolves easily in dilute acids, and is precipitated from a strong hydrochloric acid solution by ferric chloride. The platinochloride forms pale-yellow needles.

The trimethyldihydroquinoline has the constitution $C_9H_6Me_3N$ $[Me_3 = 1' : 3' : 4', \Delta = 3' : 4']$; that of the pentamethyl-derivative is not yet determined. C. F. B.

Nitrosoindole. By C. Zatti and A. Ferratini (*Ber.*, 23, 2299—2302).—To a cooled solution of indole (3 grams) in 90 per cent. acetic acid (100 grams), a concentrated solution of sodium nitrite (2 grams) is added, and the liquid poured into ice and water. The red precipitate is dried over sulphuric acid and treated with ethyl acetate; part dissolves, and part does not. The insoluble portion is dissolved in acetone, decolorised with animal charcoal, and precipitated with light petroleum. By this means brilliant, small, yellow crystals (1·3 gram) melting with decomposition at 171—172° are obtained. These are insoluble in water, ether, light petroleum, and benzene, but easily soluble in warm acetone. In acids they dissolve with partial decomposition, and give reddish solutions, which deposit reddish precipitates when diluted with water. With strong potash, they give a red solution, which deposits a red precipitate when acidified. They show all the nitroso-reactions, explode gently when ignited, yield Liebermann's colouring matters with phenol and sulphuric acid, and again form indole when reduced. All the reactions agree with the formula $CH{<}^{CH-}_{C_6H_4}{>}N{\cdot}NO$ for true nitrosoindole, but the high melting point leads one to suspect that it is a polymeride.

That part of the original precipitate which dissolves in ethyl acetate is identical with Nencki's nitroso-product, obtained by treating a saturated aqueous solution of indole with fuming nitric acid. It appears, however, not to be a true nitrosamine. C. F. B.

Synthesis of β-Indolecarboxylic Acid. By C. Zatti and A. Ferratini (*Ber.*, 23, 2296—2298).—To prepare this acid, indole (5 grams) is heated for three to four hours at 230—250°, and finally to 300° with sodium (1 gram) in a small retort through which a current of carbonic anhydride is passed. Alcohol is then added to remove the excess of sodium, the excess of alcohol evaporated, and the residue distilled with steam, so as to drive over the unaltered indole; the sodium salt of β-indolecarboxylic acid remains in the solution. The acid is precipitated on acidifying the liquid, dissolved in sodium carbonate, again liberated, and then purified by dissolving it in ethyl acetate and precipitating it with light petroleum. Its properties agree with those formerly described, except that when pure it melts at 218°, and not at 214°. A very small quantity of the α-acid is also formed in this reaction.

β-Indolecarboxylic acid, unlike the α-acid, yields no imine-anhydride when heated with acetic anhydride, but forms a mixed anhydride of β-indolecarboxylic and acetic acids, $C_8H_6N\cdot CO\cdot O\cdot COMe$. It will be remembered that an analogy to this exists among the pyrroline-derivatives; the α-carboxylic acids of this series yield imine-anhydrides, whilst the β-acids do not. C. F. B.

Constitution of Apiole and its Derivatives. By G. Ciamician and P. Silber (*Ber.*, 23, 2283—2295).—*Apionileglyoxylic* (*Apioneketonic*) *acid*, $COOH\cdot CO\cdot C_6H(OMe)_2<\begin{smallmatrix}O\\O\end{smallmatrix}>CH_2$, is formed, together with apiolic acid, when isoapiole is oxidised with alkaline permanganate, and is obtained on acidifying the solution, filtering it from precipitated apiolic acid, and extracting the filtrate with ether. It is soluble in water, ether, acetic acid, and boiling benzene, and crystallises from water in long, yellowish needles, which have no definite melting point, but decompose between 160° and 172°. It combines with phenylhydrazine hydrochloride, and its silver salt forms a white, crystalline precipitate.

When isoapiole is dissolved in alcohol and reduced with sodium, a *dihydroapiole*, $C_{12}H_{16}O_4$, is formed, and is precipitated when the solution is diluted with water. It melts at 35°, and boils at 292°, dissolves in ether, benzene, light petroleum and alcohol, and with strong sulphuric acid gives first a yellow and then a red solution. In addition to this substance, a phenol-like compound, $C_6H_2Pr(OMe)_2\cdot OH$, is formed, and can be obtained from the alkaline filtrate by evaporating the alcohol and extracting the residue with ether. It forms a rather thick, yellowish liquid, boiling at 277—278° under atmospheric pressure, and at 168° under 36 mm. It is soluble in aqueous alkalis, but not in solutions of alkaline carbonates. It dissolves slightly in warm water, and the solution gives a brown precipitate with ferric chloride. When heated with methyl iodide and potash, the hydroxyl is converted into methoxyl, but some secondary changes also occur.

By the action of bromine on isoapiole, Ginsberg obtained a tribromisoapiole; when this is boiled in alcoholic solution with zinc-dust, *monobromisoapiole*, $C_{12}H_{13}BrO_4$, is formed. This crystallises from alcohol in needles, melts at 51°, and dissolves in alcohol and ether, but not in water, and with concentrated sulphuric acid gives a brown solution. *Isoapiole dibromide*, $CH_2{:}O_2{:}C_6H(OMe)_2\cdot C_3H_5Br_2$, can be obtained by treating a cooled ethereal solution of isoapiole with bromine until a yellow colour appears. It crystallises from light petroleum in rhombic plates which melt at 75°, and are decomposed when boiled with water or alcohol, hydrobromic acid being formed. When treated with zinc-dust in alcoholic solution, an oily product, apparently different from isoapiole, is obtained. Ginsberg's tribromisoapiole is probably the dibromide of monobromisoapiole.

Apionol must have the formula $C_6H_2(OH)_4$ $[(OH_4) = 1:2:3:4]$, because it is a tetrahydroxybenzene, and is different from the symmetrical 1 : 2 : 4 : 5-tetrahydroxybenzene of Nietzki and Schmidt, and its tetramethyl-derivative is different from the 1 : 3 : 4 : 5-tetramethoxybenzene described by Will. In confirmation of this, the authors have shown that the dinitroapione obtained by nitrating apione has the nitro-groups in the ortho-positions, for the diamido-compound which it yields when reduced reacts readily with ortho-diketones forming azines. *Dinitroapione*, $C_9H_8N_2O_6$, obtained by pouring an acetic acid solution of apione into cooled nitric acid and diluting the solution with water, crystallises from alcohol in brilliant, yellow needles melting at 117—118°. By reducing it with tin and hydrochloric acid, adding excess of potash, and extracting with ether, *diamidoapione*, $C_9H_{12}N_2O_4$, was obtained; it crystallises from ether in faintly yellowish prisms melting at 119°, and dissolving in water to a yellow solution; this reduces gold and platinum chlorides, gives a green and then a reddish-brown colour with ferric chloride, and itself decomposes with deepening of colour when heated. The *hydrochloride* forms colourless, the *picrate*, yellow needles. With acetic anhydride, it yields *tetracetyldiamidoapione*, $C_9H_8O_4(NAc_2)_2$, which crystallises from alcohol in colourless needles melting at 133°. When treated with diacetyl and with benzile, azines are obtained, which have respectively the formulæ  $C_9H_8O_4{<}\begin{array}{l}N{-}CMe\\ |\quad\ \ \|\\ N{-}CMe\end{array}$ and  $C_9H_8O_4{<}\begin{array}{l}N{-}CPh\\ |\quad\ \ \|\\ N{-}CPh\end{array}$, and the melting points 176° and 222°. They both crystallise in yellow needles, and the latter gives a deep violet-red coloration with strong sulphuric acid. *Dinitrotetramethylapionol*, $C_6(OMe)_4(NO_2)_2$, obtained by pouring an acetic acid solution of tetramethylapionol into cooled nitric acid, and diluting with water, crystallises from alcohol in yellow crystals melting at 92°, soluble in alcohol, ether, and acetic acid, insoluble in water and alkalis.

Apionol having the formula given above, apione must have one of the two formulæ $C_6H_2(OMe)_2{<}^{O}_{O}{>}CH_2 = [(OMe)_2 : (O_2CH_2) = 1:2:3:4;$ or $1\cdot4:2:3]$.

Having regard to the above formula of apionol, and to the analogy between apiole and safrole, it is evident that apiole must have one of the two formulæ $C_6H(C_3H_5)(OMe)_2{<}^{O}_{O}{>}CH_2$

$$[C_3H_5 : (OMe)_2 : (O_2CH_2) = 1:2:3:4:5;\ \text{or}\ 1:2:5:3:4].$$

And, as in the reduction of isoafrole (this vol., p. 966), the oxygen in the para-position to the allyl-group is the one which is lost; hence the phenol-compound obtained by reducing isoapiole has one of the two formulæ $C_6H_2(C_3H_7)(OMe)_2\cdot OH$ $[C_3H_7 : (OMe)_2 : OH = 1:2:3:5;$ or $1:2:5:3]$. The corresponding trimethoxy-compound can only have one formula $[C_3H_7 : (OMe)_3 = 1:2:3:5]$; it is not, however, identical with the compound obtained by reducing Will's asarone, $C_6H_2(C_3H_5)(OMe)_3$, probably $= 1:2:4:5$.

The C_3H_5-group in apiole is probably allyl; in isoapiole, propenyl; and this is the cause of the isomerism of those two substances.

C. F. B.

Trimethylphenylmethane. By M. Seńkowski (*Ber.*, 23, 2412—2420).—Trimethylphenylmethane has previously been obtained; it is best prepared by treating benzene (3 parts) with isobutyl chloride (1 part) and aluminium chloride (1 part) for two days, the temperature never being allowed to exceed 4°. The product is poured into a mixture of ice and water and distilled in a current of steam, the distillate is washed, fractionated, and the portion boiling at 167—168° treated with bromine in direct sunlight; after further washing, the product is finally distilled over sodium. The pure hydrocarbon boils at 167—167·5°; the yield is 70 per cent. of the theory. Trimethylphenylmethane dissolves in excess of nitric acid, and on pouring the product into water and fractionating the oil which separates, two isomeric nitro-compounds are obtained; they are probably ortho- and para-derivatives, although there is no direct proof. *Orthonitrophenyltrimethylmethane*, $CMe_3{\cdot}C_6H_4{\cdot}NO_2$, is a yellow, viscid liquid, of sp. gr. 1·074 at 15°; it boils at 247·4—248·4° under a pressure of 737·8 mm., and is miscible with ether, alcohol, or benzene. *Orthamidophenyltrimethylmethane*, $CMe_3{\cdot}C_6H_4{\cdot}NH_2$, is obtained by the reduction of the nitro-compound with tin and hydrochloric acid; it is a colourless, oily, strongly refractive liquid, of sp. gr. 0·9769 at 15°; it boils at 233—235°, and becomes coloured on exposure to air. The *sulphate* is sparingly soluble in water, from which it crystallises in plates. The *hydrochloride* is deposited in small needles. The *nitrate* crystallises in needles, and dissolves most readily in water. The *platinochloride* is obtained as an insoluble, yellow, crystalline precipitate. All these salts remain unchanged on exposure to air. The *acetyl-derivative*, $CMe_3{\cdot}C_6H_4.NHAc$, crystallises from benzene in radiating groups of long needles melting at 159°.

Paranitrophenyltrimethylmethane crystallises from alcohol in yellow needles melting at 30°, and boiling at 274·6—275° under a pressure of 737 8 mm. *Paramidophenyltrimethylmethane* resembles the ortho-compound; it boils at 239 4—240·4° under a pressure of 739·2 mm., and has a sp. gr. of 0·9525 at 15°. The *sulphate* crystallises from water in long, colourless, lustrous needles; the *nitrate* is readily soluble; the *hydrochloride* and *platinochloride* crystallise from water in needles. The *acetyl-derivative* is deposited from benzene in long, flat needles melting at 172°. Both the ortho- and para-amines give a yellow colour with ferric chloride.

Paratertiarybutylbenzenesulphonic acid, $CMe_3{\cdot}C_6H_4{\cdot}SO_3H$, is prepared by treating the hydrocarbon with fuming sulphuric acid at ordinary temperatures; it is a very hygroscopic, white, crystalline powder, melting at 62—63°; it appears to be the only sulphonation-product. The *potassium salt*, $CMe_3{\cdot}C_6H_4{\cdot}SO_3K + H_2O$, is sparingly soluble in cold water, and crystallises in plates. The *calcium salt*, $(C_{10}H_{13}{\cdot}SO_3)_2Ca + 4H_2O$, is deposited from water in plates. *Paratertiarybutylphenol*, $CMe_3{\cdot}C_6H_4{\cdot}OH$, is prepared by fusing the potassium sulphonate with potassium hydroxide; it may also be obtained from the amido-derivative by means of the diazo-reaction. It is a white, crystalline powder, melting at 98·5°, and boiling at 238—239° under a pressure of 737 mm.; it sublimes at about 100°, and forms long needles, readily soluble in alcohol, ether, and alkalis; it has an odour resembling that of Russian leather. The *methoxy-derivative*, $CMe_3\cdot C_6H_4\cdot OMe$, is obtained by the action of methyl iodide on the potassium phenoxide; it is a colourless liquid of sp. gr. 0·9439 at 15°, and boils at 221·4—222·4° under a pressure of 730·5 mm. The *ethoxy-derivative*, $CMe_3\cdot C_6H_4\cdot OEt$, closely resembles the preceding compound; it boils at 233—233·6° under a pressure of 730·5 mm., and has a sp. gr. of 0·9331 at 15°.

Tertiary dibutylbenzene, $C_6H_4(CMe_3)_2$, is separated from the higher-boiling fractions obtained during the purification of tertiary butylbenzene; it is readily soluble in alcohol, and is deposited in long crystals melting at 70°, and boiling at 235—235·5° under a pressure of 736·5 mm.

Tertiary tributylbenzene, $C_6H_3(CMe_3)_3$, is formed together with the previous compound; it crystallises from alcohol in scales melting at 128°, and boiling at 291—292° under a pressure of 736·6 mm. A liquid hydrocarbon boiling about 227—230° is also formed in small quantity.
J. B. T.

Carbazoledisulphonic Acid. By J. Bechhold (*Ber.*, **23**, 2144—2146).—Pure carbazoledisulphonic acid, $C_{12}H_7N(SO_3H)_2$, can be prepared in the following manner:—Carbazole is warmed for a short time with sulphuric acid of sp. gr. 1·84, the product poured into water, the solution neutralised with barium carbonate and evaporated. The mixture of barium mono- and di-sulphonate obtained in this way is purified by repeatedly dissolving it in water and reprecipitating with alcohol, but it cannot be obtained in crystals; on decomposition with sulphuric acid, it yields the free acids in the form of a gelatinous precipitate, which is almost insoluble in alcohol, but soluble in water. When the crude acid mixture is dissolved in water, and a 3 per cent. solution of potassium permanganate gradually added until a permanent coloration is produced, all impurities are destroyed, and the filtered solution, on evaporation, yields the salt $C_{12}H_7N(SO_3K)_2$ in yellowish crystals. The free disulphonic acid, prepared by decomposing a concentrated solution of the potassium salt with hydrofluosilicic acid, adding a little alcohol, and evaporating the filtered solution, crystallises in colourless needles, and decomposes at a high temperature, but without melting. When the potassium salt is heated with concentrated hydrochloric acid at 200°, it yields pure carbazole.
F. S. K.

Benzidine. By H. Schiff and A. Vanni (*Chem. Centr.*, 1890, i, 941—942; from *L'Orosi*, **13**, 1).—By the action of diethylbenzidine (1 mol.) and phthalic anhydride (1 mol.), *phthalyldiethylbenzidine*,

$C_6H_4\Big<\begin{matrix}CO\cdot NEt\cdot C_6H_4\\ \vert\\ CO\cdot NEt\cdot C_6H_4\end{matrix}$, is obtained. It forms small, yellow crystals, which melt at 250° with decomposition. It is slightly soluble in cold alcohol, but almost insoluble in water, ether, and chloroform, or in cold acids, or caustic alkalis. If allowed to remain with alcoholic potash for some time at ordinary temperatures, *potassium diethylbenzidinephthalate* is formed, from which the free acid may be obtained by the action of hydrochloric acid; it is, however, not very stable.

Tetrethylbenzidine (1 mol.) and phthalic anhydride (2 mols.) combine together directly to form *tetrethylbenzidinephthalic acid*, $C_{36}H_{36}N_2O_6$. It is a white powder, readily soluble in alcohol and chloroform, insoluble in water, ether, and light petroleum. If the alcoholic solution is boiled for a short time, or if it is treated with alkalis in the cold, decomposition sets in. Hydroxylamine and phenylhydrazine do not react with it.

Ethyl chlorocarbonate reacts with benzidine, forming *benzidinediurethane*, $COOEt\cdot NH\cdot C_6H_4\cdot C_6H_4\cdot NH\cdot COOEt$, which melts at 230°. It forms colourless needles, insoluble in water, sparingly soluble in ether and light petroleum, readily in boiling alcohol. Alcoholic ammonia partially converts it into benzidinesemiurethane. By boiling it with aniline, it is converted into benzidine, alcohol, and diphenylcarbamide; by boiling it with pure benzidine, it forms benzidine, alcohol, and probably a polymeride of benzidinecarbamide. These reactions do not take place in alcoholic solution.

When benzidine (2 mols.) and ethyl chlorocarbonate (2 mols.) react, benzidinediurethane, benzidine hydrochloride, and a considerable quantity of *benzidinesemiurethane hydrochloride*

$$COOEt\cdot NH\cdot C_6H_4\cdot C_6H_4\cdot NH_2,HCl,$$

are formed. The free urethane is obtained from the hydrochloride by treatment with sodium carbonate. It is an amorphous, grey powder, melting at 90°, readily soluble in alcohol, sparingly in boiling water. The acetate dissolves in acetic acid, alcohol, and light petroleum, but is almost insoluble in water and ether. With salicylaldehyde, it forms the compound

$$COOEt\cdot NH\cdot C_6H_4\cdot C_6H_4\cdot N{:}CH\cdot C_6H_4\cdot OH,$$

readily soluble in light petroleum, sparingly in ether; it melts at 170°. It is insoluble in potassium hydroxide; it gives no reaction with ferric chloride. With glyoxal, it forms the compound

$$COOEt\cdot NH\cdot C_{12}H_8\cdot NH\cdot CH(OH)\cdot CH(OH)\cdot NH\cdot C_{12}H_8\cdot NH\cdot COOEt.$$

This is a yellow powder, which is soluble in alcohol, and decomposes on exposure to the air. The following condensation-products are obtained with benzidine and aldehydes. *Salicylbenzidine*, $C_{12}H_8N_2(C_7H_6\cdot OH)_2$, crystallises from boiling benzene in lustrous, colourless needles, which melt at 264°; they become yellowish when exposed to the air. *Metanitrobenzylidenebenzidine*, $C_{12}H_8N_2(C_7H_5\cdot NO_2)_2$, separates from boiling benzene in small, orange-yellow crystals, sparingly soluble in water, and melting at 234°. *Cumylidenebenzidine*, $C_{12}H_8N_2(C_{10}H_{12})_2$, forms lustrous plates, which melt at 268°. Acetaldehyde forms a compound which may be considered as *amidophenylenequinaldine*,

$$NH_2\cdot C_6H_4\cdot C_6H_3<\begin{array}{l}N{=}CMe\\ \quad\ \ |\\ CH{:}CH\end{array} + \tfrac{1}{2}H_2O.$$

It is a white powder, nearly insoluble in the usual solvents, sparingly soluble in chloroform. *Isobutylenebenzidine*, $C_{12}H_8N_2(C_4H_8)_2$, readily soluble in light petroleum, melts at 230° with decomposition. *Œnanthylidenebenzidine*, $C_{12}H_8N_2(C_7H_{14})_2$. forms small, white crystals melting at 112—115°, and readily soluble in light petroleum.

Tolidine forms analogous compounds with aldehydes; *cumylidenetolidine*, $C_{12}H_6Me_2N_2(C_{10}H_{12})_2$, crystallises from a mixture of alcohol and light petroleum in needles; it melts at 152°. *Cinnamylidenetolidine*, $C_{12}H_6Me_2N_2(C_9H_8)_2$, crystallises from light petroleum; it melts at 213—214°. *Furotolidine*, $C_{12}H_6Me_2N_2(C_5H_4O)_2$, crystallises from light petroleum in lustrous, gold plates; it melts at 192°. The author finds that benzidine is sparingly soluble in boiling water, 1 part dissolving in 106·5 parts. J. W. L.

Isomerism in the Stilbene-group. By P. WALDEN and A. KERNBAUM (*Ber.*, **23**, 1958—1961).—It has been shown by Bischoff (Abstr., 1888, 1094) that orthonitrostilbene forms two isomerides, corresponding with fumaric and maleïc acids. The authors find that paranitrostilbene, obtained by the action of alcoholic potash on paranitrobenzyl chloride, also forms two geometrical isomerides. The one crystallises in pale-yellow needles which melt at 280—285°, and are readily soluble in hot acetic acid, aniline, acetone, and ethylene bromide, sparingly in alcohol, ether, chloroform, and benzene. The second isomeride crystallises in reddish-yellow needles melting at 210—216°, and is less soluble than the first compound in ether and alcohol, but dissolves more readily in acetone, benzene, and chloroform. H. G. C.

Contributions to the Theory of Six-membered "Rings." By E. BAMBERGER (*Annalen*, **257**, 1—55).—The investigations of the author and his pupils on the reduction of the amines and phenols of naphthalene in boiling amyl alcohol solution by means of sodium (Abstr., 1888, 159, 599, 712, 959; 1889, 715, 717, 737, 782, 888, 891, 892, 1000, 1198; this vol., pp. 506, 508, 627, 631) show that in every case four atoms of hydrogen are taken up asymmetrically, that is, are added on to one of the rings and not distributed between the two. The effect of reduction on the properties of the substance depends entirely on the distribution of the added hydrogen-atoms: "alicyclic" derivatives, which contain both the substituent and the added hydrogen-atoms in the same nucleus, react like fatty amines or alcohols, whilst "aromatic" derivatives, which contain the substituent in one and the added hydrogen atoms in the second nucleus, exhibit the aromatic characters of the parent substances, but in a more marked degree, the properties of ar.-tetrahydro-α-naphthylamine, for example, approximating more to those of aniline than to those of α-naphthylamine.

Dealing with "aromatic" tetrahydro-compounds, the author cites the following evidence to prove that the peculiar properties which distinguish derivatives of naphthalene from those of benzene disappear on hydrogenation. An aqueous solution of 1:4-naphthylenediamine sulphate to which sodium acetate and aniline hydrochloride have been added, becomes reddish-brown on treatment with potassium dichromate, and gives a dirty brown, flocculent precipitate. ar.-Tetrahydro-1 : 4-naphthylenediamine, when oxidised under similar conditions, behaves like paraphenylenediamine in forming an indamine and a saffranine. *Tetrahydronaphthindamine* is precipitated in glistening, bronze-green crystals on the addition of salt to its green aqueous solution, and exhibits all the characters of an indamine; when boiled with dilute acid, it decomposes into tetrahydro-α-naphthaquinone, which is volatile with steam, and is readily recognised by its pungent odour. Again, an acidified solution of 1 : 4-naphthylenediamine containing hydrogen sulphide, when treated with ferric chloride, gives a dull, dark-brown, flocculent precipitate, the liquid becoming yellowish-brown. ar.-Tetrahydro-1 : 4-naphthylenediamine, on the contrary, behaves like paraphenylenediamine under these conditions, and is converted into a thionine. *Tetrahydronaphthathionine* crystallises in lustrous, slender, dark-violet needles showing a metallic lustre, and readily dyes silk and wool producing a dark-violet shade. Further, the dichlorodiimides of 1 : 4-naphthylenediamine and paraphenylenediamine differ in the colours they give with aromatic bases, and comparison shows that the colours obtained with tetrahydro-1 : 4-naphthylenedichlorodiimide under similar conditions resemble those from the latter rather than those from the former. *ar.-Tetrahydro-*1 : 4-*naphthylenedichlorodiimide*, $C_{10}H_{10}(NCl)_2$, crystallises from ether in long, silky, yellowish-white needles, melts at 68°, is sparingly soluble in water, but readily in the usual organic solvents, and gives a violet colour when warmed with an alcoholic aniline solution and hydrochloric acid, and an emerald-green with dimethylaniline.

As evidence that naphthalene compounds on conversion into "aromatic" tetrahydro-derivatives lose their specific naphthalene characters, the author adduces the following examples amongst others. The naphthols yield alkyl-derivatives when heated at 150° with alcohol and hydrochloric acid (Liebermann and Hagen, Abstr., 1882, 1212), but the "aromatic" tetrahydronaphthols, like phenol and most of its homologues, are not acted on under similar conditions. The naphthols can readily be converted into naphthyl sulphates (Nietzki, Abstr., 1882, 736), but the "aromatic" tetrahydronaphthols resemble phenol in not forming sulphates. α- and β-Naphthaquinone react with phenylhydrazine forming hydrazones (Zincke, *Ber.*, 18, 786, footnote), but ar.-tetrahydro-α-naphthaquinone, under like conditions, is reduced to ar.-tetrahydro-α-naphthaquinol, the resemblance to ordinary quinone being further marked by the close similarity in crystalline character, volatility, colour, odour, &c.

The alteration in properties involved in the reduction of naphthalene-derivatives to "aromatic" tetrahydro-bases is strikingly shown by the marked resemblance in properties of ar.-tetrahydro-α-naphthylamine to 1 : 2 : 3-orthoxylidine, and of ar.-tetrahydro-α-naphthol to 1 : 2 : 3-orthoxylenol.

With reference to "alicyclic" reduction, it is already known that "alicyclic" tetrahydro-derivatives have all the characters of fatty amines or alcohols; the author, in this connection, points out that the properties of ac.-tetrahydro-β-naphthylamine and ac.-tetrahydro-β-naphthol are identical with those which β-amido- or β-hydroxyorthodiethylbenzene would be expected to have, and further shows that ac.-tetrahydro-β-naphthylamine closely resembles the known phenylethylamine in properties, the similarity being especially marked in the case of the nitrites of the two compounds, which can be crystallised from boiling water, and when decomposed are converted, with elimination of ammonia, into unsaturated hydrocarbons, the former yielding dihydronaphthalene (Bamberger and Müller, Abstr., 1888, 712), the latter cinnamene (Fileti and Piccini, Abstr., 1879, 922).

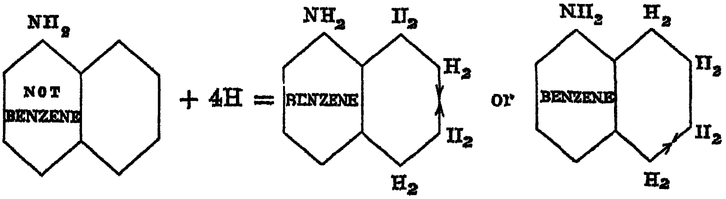
The consideration of these points leads to the deduction of the following laws:—

I. In naphthalene, and those of its derivatives in which each of the eight carbon atoms is united with a monad radicle, two carbon systems are present, neither of which exists as a benzene-ring, but is converted into one when the second takes up four atoms of hydrogen.

II. The effect of the addition of four atoms of hydrogen to either of the two carbon systems of naphthalene and its derivatives is to cause that system to assume the properties of an open (fatty) chain.

III. Tetrahydrogenation in the naphthalene series results in the product reacting as if it were a benzene-derivative with a fatty side-chain. The hydrogenated system assumes the fatty, and the non-hydrogenated the benzene functions.

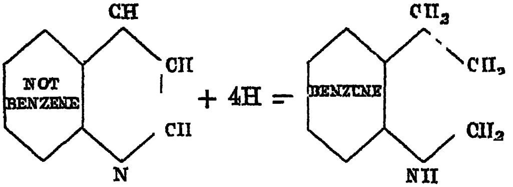
Graphically, the reduction of α-naphthylamine can be represented as follows, the chain with arrow-heads indicating a ring with fatty functions:—



In connection with the first law, the author discusses the various formulæ hitherto proposed for naphthalene, and discards them as inadequate, since they all fail to give expression to the view that a ring system which is *similar* to benzene becomes *identical* with it by reduction.

As an investigation of naphthalene-derivatives with the object of accumulating experimental evidence of the change in the character of the rings could hardly lead to any satisfactory result, the author has employed a compound with dissimilar rings, choosing quinoline for this purpose—the assumption being made that the atomic arrangement and distribution of valency corresponds exactly in quinoline and naphthalene.

On reduction, quinoline exhibits the properties of an alkylated aniline, the pyridine ring which takes up the four hydrogen-atoms assuming the character of a side-chain:—

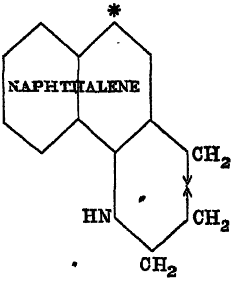


Quinoline. Tetrahydroquinoline.

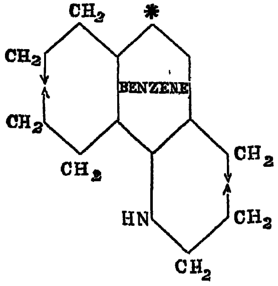
As evidence of this change in properties, the author quotes the resemblance of kairoline (1'-methyltetrahydroquinoline) to dimethylaniline (Feer and Koenigs, *Ber.*, 18, 2389), the intramolecular change of the nitrosamine of tetrahydroquinoline into 3-nitrosotetrahydroquinoline (Ziegler, Abstr., 1888, 609), and the fact that tetrahydroquinoline, unlike quinoline but like dimethylaniline, forms a condensation compound with benzaldehyde analogous to leuco-malachite-green (Einhorn, *Ber.*, 19, 1243). Further, the action of diazobenzenesulphonic acid on tetrahydroquinoline forms *sulphophenylazotetrahydroquinoline*, $C_{15}H_{15}N_3SO_3$, which crystallises in dark steel-blue needles with a metallic lustre, dissolves in aqueous soda with a dark-red colour, and, on reduction with stannous chloride, is converted into Ziegler's 3-amidotetrahydroquinoline (*loc. cit.*). Tetrahydroisoquinoline, as anticipated, does not form azo-dyes under these conditions, and closely resembles benzylamine in its properties.

Substituted quinolines behave as quinoline does on reduction. Ziegler's 3-amidotetrahydroquinoline, unlike 3-amidoquinoline, exhibits the characters of a true phenylenediamine; thus, it gives the indamine and saffranine reactions when oxidised in the presence of aniline hydrochloride, forms dyes of the character of tolylene-blue and tolylene-red when treated with metaphenylenediamine and potassium dichromate, of the character of indoanilines with phenols and potassium dichromate, and of methylene-blue with hydrogen sulphide and ferric chloride. 2- and 4-hydroxyquinoline do not give dyes when heated with phthalic anhydride and zinc chloride, but their tetrahydro-derivatives, like metamidophenol, are converted under these conditions into *rhodamines*, which closely resemble ordinary rhodamine in properties, except that they produce less blue shades on silk and wool. It is further pointed out that the conversion of the methiodide of 1-hydroxykairoline (1-hydroxytetrahydro-1'-methylquinoline) into 1-methoxykairoline by treatment with caustic alkali (Fischer and Kohn, *Ber.*, 19, 1040; Kohn, Trans., 1886, 501) corresponds with the conversion of the methiodide of dimethylorthamidophenol into methoxydimethylorthamidobenzene under similar conditions (Griess, Abstr., 1880, 637), since the "ring" containing the nitrogen-atom has only the configuration, and not the essential properties of a (pyridine) ring.

Naphthaquinolines, generally, do not react with diazo-compounds. Of the hydrogenated bases examined, py.-tetrahydro-α-naphthaquinoline, ar.-octohydro-α-naphthaquinoline, ar.-octohydro-β-naphthaquinoline, and ar.-octohydro-β-quinaldine give azo-colours, whilst py.-tetrahydro-β-naphthaquinoline, py.-tetrahydro-β-naphthaquinaldine, ac.-octohydro-β-naphthaquinoline, ac.-octohydro-β-naphthaquinaldine, and di-β-tetrahydro-α-naphthaquinoline do not. Inspection of the formulæ gives the explanation of these differences, when the conditions attending the formation of azo-dyes in the benzene and naphthalene series are borne in mind. Thus, for example, with the α-compounds:—

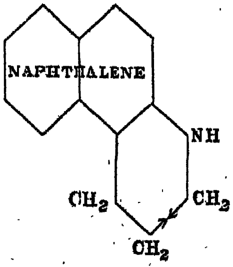


py.-Tetrahydro-
α-naphthaquinoline.

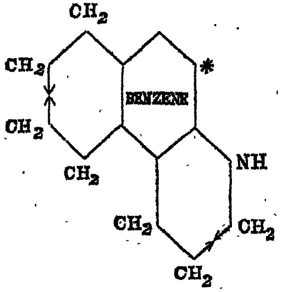


ar.-Octohydro-
α-naphthaquinoline.

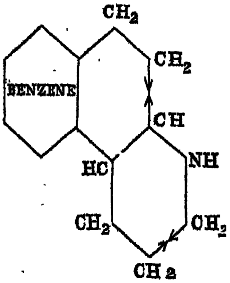
py.-Tetrahydro-α-naphthaquinoline behaves like an alkylated α-naphthylamine, and ar.-octohydro-α-naphthaquinoline like an alkylated aniline, the azo-group taking up the para-position to the nitrogen atom. With the β-compounds—



py.-Tetrahydro-
β-naphthaquinoline.



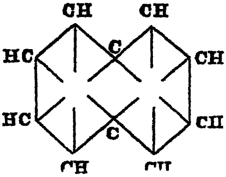
ar.-Octohydro-
β-naphthaquinoline.



ac.-Octohydro-
β-naphthaquinoline.

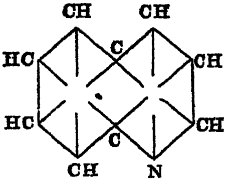
py.-Tetrahydro-β-naphthaquinoline reacts as an alkylated β-naphthylamine but cannot form colours since the contiguous α-position is occupied; ar.-octohydro-β-naphthaquinoline behaves like an alkylated aniline, and the para-position to the nitrogen-atom being closed, forms an ortho-azo-dye, whilst ac.-octohydro-β-naphthaquinoline reacts as an alkylated benzylamine, and does not give azo-dyes but diazoamido-derivatives by the action of diazo-compounds.

Returning to the discussion of naphthalene formulæ, it is pointed out that the Claus formula is based on the supposed asymmetry of the naphthalene molecule (*Ber.*, **9**, 590, 1606; **10**, 1303). No valid evidence of this asymmetry has been adduced, and as a further argument for the symmetry of the molecule, the author shows that 2 : 2′-dihydroxynaphthalene, like β-naphthol, is readily etherified by digestion with alcohol and sulphuric acid on a water-bath. From a consideration of the three laws already quoted (*v. supra*) and the symmetry of the molecule, the author is led to extend Armstrong's and v. Baeyer's conception of the benzene molecule (Trans., 1887, 264; *Annalen*, **245**, 128) to naphthalene, and to assign to the latter the symbol—



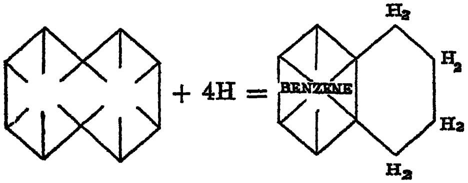
Naphthalene.

whence



Quinoline.

Such a symbol represents naphthalene as composed of two similar carbon-systems, neither of which is identical with, although similar to, a benzene ring. The effect of hydrogenation on the molecule, and conversion of one of the systems into a ring identical with that of benzene, is represented by the graphic equation—



The remainder of the paper is devoted to a discussion of this formula, and the extension of the conception to more complex ring-compounds, such as anthracene and phenanthrene. W. P. W.

Characteristics of the Hydrogenation Process. By E. Bamberger and F. Lengfeld (*Ber.*, **23**, 1124—1137).—ar.-Tetrahydro-α-naphthol does not give a trace of tetrahydronaphthyl sulphate when treated with concentrated sulphuric acid in the cold, of tetrahydronaphthyl ethyl ether when heated with an equal weight of 39 per cent. hydrochloric acid and three times its weight of absolute alcohol for 7—8 hours at 150°, or of dinaphthyl ether when boiled with 2½ times its weight of dilute sulphuric acid (1 : 1), and differs therefore from α-naphthol in all these reactions. With sodium nitrite and concentrated sulphuric acid, it gives a brownish-red colour, which, after the addition of water and caustic soda, becomes yellowish-green, whilst it gives no colour reaction either with bleaching powder or with ferric chloride, thus resembling 1 : 2 : 3-orthoxylenol.

ar.-Tetrahydro-β-naphthol is not etherified by heating with concentrated sulphuric acid and absolute alcohol on a water-bath for seven hours, and does not form a trace of tetrahydronaphthyl sulphate when treated with concentrated sulphuric acid in the cold.

ar.-Tetrahydro-α-naphthaquinone, $C_{10}H_{10}O_2$, can be prepared from ar.-tetrahydro-α-naphthylamine by oxidation with sodium dichromate and dilute sulphuric acid on the lines of Nietzki's quinone-process, the yield amounting to 20 per cent. of the theoretical. It closely resembles quinone in odour, volatility, colour, lustre, solubility, crystalline character, &c.; melts at 55·5° (that is, within half a degree of orthoxyloquinone), and is reduced to ar.-tetrahydro-α-naphthaquinol by treatment with phenylhydrazine.

ar.-Tetrahydro-α-naphthaquinol, $C_{10}H_{10}(OH)_2$, may be obtained by digesting ar.-tetrahydro-α-naphthaquinone for 48 hours with sulphurous acid at the ordinary temperature of the air, boiling the colourless aqueous solution for a few minutes, and finally extracting with ether. It closely resembles quinol in properties, crystallises in aggregates of slender, colourless prisms, sublimes without decomposition in beautiful needles, melts at 172—172·5°, and is soluble in the ordinary organic solvents and in hot water. By careful oxidation with potassium dichromate in the cold, it can be converted into the *quinhydrone*; further oxidation results in the formation of ar.-tetrahydro-α-naphthaquinone.

ar.-Tetrahydro-α-naphthylamine resembles α-naphthylamine rather than aniline in forming an amidoazo- instead of a diazoamido-compound on treatment with diazo-compounds. *ar.-Amidoazotetrahydro-α-naphthalene*, $C_{10}H_{11}\cdot N_2\cdot C_{10}H_{10}\cdot NH_2$, is obtained by the action of amyl nitrite (1 mol. prop.) on the tetrahydro base (2 mol. props.), or by diazotising a mixture of the tetrahydro-base (1 mol. prop.) and its hydrochloride (1 mol. prop.) with sodium nitrite (1 mol. prop.). It crystallises from alcohol in orange-red, lustrous needles, melts at 141°, and is readily soluble in benzene, chloroform, ether, light petroleum and boiling alcohol, insoluble in water. W. P. W.

Action of Sulphurous Anhydride on Nitroso-compounds.

By M. Schmidt (*J. pr. Chem.* [2], 42, 156—157).—Acetone and amidosulphonic acid are produced when sulphurous anhydride acts on acetoxime, $CMe_2{:}NOH$, in aqueous solution.

α-Nitroso-β-naphthol and β-nitroso-α-naphthol both give amidosulphonic acids when sulphurous anhydride is passed into their alcoholic solutions or when they are dissolved in sodium hydrogen sulphite and the solution decomposed by hydrochloric acid; but α nitroso-α′-naphthol does not give a similar result.

The amidonaphtholsulphonic acid from α-nitroso-β-naphthol crystallises in colourless needles (with ½ mol. H_2O), which gradually become red; it is insoluble in the usual solvents, but dissolves in sodium acetate and hot sodium hydrogen sulphite solutions; the latter solution has a blue fluorescence. The acid is easily oxidised, reducing ammoniacal silver solutions.

The amidosulphonic acid from β-nitroso-α-naphthol crystallises in stellate groups of needles (with 1½ mols. H_2O); in properties it resembles the other acid.
A. G. B.

αα-Dithionaphthol. By L. Grosjean (*Ber.*, 23, 2370—2371; compare Abstr., 1889, 715).—αα-Dithionaphthol, $C_{10}H_6(SH)_2$, is prepared by treating sodium αα-naphthylenedisulphonate (10 parts) with phosphorus pentachloride (14 parts), and pouring the product into a mixture of 210 parts of dilute sulphuric acid (1 : 2·5) and 35 parts of zinc-dust. When the reduction is completed, the insoluble portion is separated, washed, dried, and extracted with ether. After evaporation of the ether, the residue is purified by distillation, and crystallisation from alcohol, from which it is deposited in lustrous plates melting at 180—181°, and boiling at 210° under a pressure of 15 mm. The compound is very sparingly soluble in ether, light petroleum, or toluene; the alcoholic solution gives a deep-yellow precipitate with lead acetate; in the dry state it is not acted on by air, but in alkaline solution it readily oxidises with formation of a white powder soluble in aniline; on adding hydrochloric acid, this is precipitated unchanged, and remains solid at 220°.

Benzoyldithionaphthol, $C_{10}H_6(SBz)_2$, is prepared by the action of benzoic chloride, and is deposited from alcohol in lustrous crystals melting at 152—153°. The *acetyl*-derivative, $C_{10}H_6(SAc)_2$, is obtained by means of acetic chloride; it separates from alcohol in colourless crystals melting at 110°.
J. B. T.

Thio-derivatives of Aromatic Amines. By O. Kym (*Ber.*, 23, 2458—2468; compare Abstr., 1889, 51).—*Benzoylthio-β-dinaphthylamine*, $S{<}\substack{C_{10}H_6\\C_6H_{10}}{>}NBz$, is prepared by heating thio-β-dinaphthylamine with benzoic anhydride at 210°; the product is treated with aqueous sodium hydroxide, and purified by dissolving in benzene; on the addition of light petroleum or alcohol to this solution, it crystallises out in groups of almost colourless needles, melting at 196—197°. It dissolves sparingly in alcohol or ether, and is insoluble in light petroleum.

Methylthio-β-dinaphthylamine, $S{<}\substack{C_{10}H_6\\C_{10}H_6}{>}NMe$, is obtained by heating thio-β-dinaphthylamine with methyl iodide and methyl alcohol at 150°; after repeated crystallisation from benzene, it is deposited in lemon-yellow plates, or slender needles, melting at 284—285°. It is readily soluble in toluene, but more sparingly in benzene and alcohol. With concentrated sulphuric acid, a violet colour is gradually produced, which instantaneously changes to deep blue on the addition of nitric acid. The same compound is also formed on heating sulphur with methyl-β-dinaphthylamine at 240°, or by treatment with a benzene solution of sulphur mono- or dichloride at ordinary temperatures. No dithio-derivative could be isolated in these experiments. The methyl-β-dinaphthylamine employed melted constantly at 123—124°, instead of 139—140°, as given by Ris (compare Abstr., 1888, 57).

Ethylthio-β-dinaphthylamine,  $S<\substack{C_{10}H_6\\C_{10}H_6}>NEt$, is prepared from thio-β-dinaphthylamine by the action of ethyl iodide, and from ethyl-β-dinaphthylamine by the action of sulphur mono- and di-chlorides. It crystallises from benzene in small tufts of bright-yellow needles melting at 212—213°, and resembles the methyl-derivative in general properties.

Thiophenyl-α-naphthylamine,  $S<\substack{C_{10}H_6\\C_6H_4}>NH$, is obtained on heating phenyl-α-naphthylamine with sulphur at 240°: the product is treated with benzene, and on recrystallisation from alcohol, it is deposited in small, yellow, lustrous plates melting at 137—138°. It gives a deep blue colour with concentrated sulphuric acid, which changes to red on adding nitric acid

By heating crude thiophenyl-α-naphthylamine with recently-reduced, finely-divided copper at 280° for three hours, *phenyl-α-naphthylcarbazole*,  $\begin{matrix}C_{10}H_6\\|\\C_6H_4\end{matrix}>NH$, is formed; it crystallises from dilute alcohol in small, pale, yellowish-green, lustrous plates, melts at 225°, and is readily soluble in glacial acetic acid, benzene, or alcohol, but insoluble in light petroleum.

Thiophenyl-β-naphthylamine,  $S<\substack{C_{10}H_6\\C_6H_4}>NH$, is prepared from phenyl-β-naphthylamine and sulphur; it crystallises from dilute alcohol in tufts of lustrous, light-yellow needles, melting at 178°, and resembling the isomeric compound described above in general properties. With concentrated sulphuric acid, it gives a deep-blue colour, changing to deep-violet on the addition of nitric acid. No carbazole-derivative could be obtained, as the compound may be distilled over heated copper without undergoing any change.

Methylthiophenyl-β-naphthylamine,  $S<\substack{C_{10}H_6\\C_6H_4}>NMe$, is formed by the action of methyl iodide on thiophenyl-β-naphthylamine; it crystallises from a mixture of benzene and alcohol in groups of pale, yellowish-green needles, melting at 132—133°. With concentrated sulphuric acid, it gives a deep-blue colour which is not altered by nitric acid.

J. B. T.

Cyanamines, a New Group of Dyes. By O. N. Witt (*Ber*, 23, 2247—2252). The dye called naphthol-violet, which was first prepared by the author and Meldola (Trans., 1881, 37) simultaneously, by treating nitrosodimethylaniline hydrochloride with β-naphthol, is a mixture of several compounds which have, however, one property in common, namely, that when viewed by artificial light they appear red. The magenta-red dye obtained by Nietzki and Otto (Abstr., 1888, 949) from β-naphthol and quinonedichlorimide seems to be homogeneous, and has probably the constitution assigned to it by him.

When the free bases of these two dyes are warmed, they become insoluble in ether, and are finally converted into substances of quite different appearance; when redissolved in acids, these new compounds both give dyes which have a greenish-blue shade, even when viewed by artificial light. Other dyes of the same group as naphthol-violet, such as the violet obtained from methyldihydroxynaphthalene, show a like behaviour, and the reaction is probably a general one. The author gives the name "cyanamine" to this class of new dyes.

The *cyanamine*, $C_{26}H_{26}N_4O_2$, formed from Meldola's β-naphthol-violet is best obtained by heating the freshly-prepared dye with an alcoholic solution of calcium hydroxide for 1 to 1½ hours. The crystalline base is separated by filtration, washed with alcohol and water consecutively, then extracted with boiling alcohol, the residue dissolved in dilute hydrochloric acid, and the base precipitated from the boiling solution by ammonia. It crystallises from chloroform in blackish-brown plates, and is insoluble, or almost insoluble, in most ordinary solvents except chloroform, its solution being of a reddish-violet shade. It dissolves in concentrated acids yielding brownish-orange, and in dilute acids yielding blue solutions. The *sulphate* separates from alcohol in shining green scales, the *hydrochloride*, $C_{26}H_{26}N_4OCl_2$, in plates or prisms of the same colour; both compounds are readily soluble in water, by which they are partially converted into violet basic salts. The base is oxidised by chromic acid to a new violet-blue dye, the base of which is orange-red, and dissolves in ether yielding a yellow, fluorescent solution.

The constitution of the cyanamine base is probably expressed by the formula—

$$NMe_2\cdot C_6H_4\cdot\overset{4}{N}\underset{1'}{\overset{O\ \ 2'}{\diagup\!\diagdown}}C_{10}H_5\cdot\overset{4'}{N}\overset{1\ C_6H_4\ 4}{\diagup\!\diagdown}NMe_2\cdot OH.$$

F. S. K.

Constitution of Diphenyl- and Phenylnaphthylamine-Blue.

By A. HAUSDÖRFER (*Ber.*, 23, 1961—1966).—Diphenylamine-blue was prepared according to Schoop's method (*Zeit. angew. Chem.*, 1887, 215), by heating diphenylamine with oxalic acid at 130—132°, extracting the product with boiling water, heating with alcohol, and precipitating with hydrochloric acid. It forms a brownish-red powder, which is soluble in hot aniline and nitrobenzene, less so in hot acetone, acetic acid, and alcohol. It dissolves in alcoholic potash forming a brownish-red solution, from which the colouring matter is reprecipitated by acids. It also dissolves in sulphuric acid, and is reprecipitated by water in blue flocks. After recrystallisation from acetic acid, it gave numbers agreeing with the formula $CCl(C_6H_4\cdot NHPh)_3$. In support of this formula is the fact that it is readily converted into a leuco-base on reduction, which on oxidation with chloranil again forms the original colouring matter. Moreover it is identical with the blue obtained from pararosaniline, the so-called triphenylpararosaniline.

When phenyl-α-naphthylamine and oxalic acid are heated together in a similar manner, the corresponding phenyl-α-naphthylamine-blue, $CCl(C_6H_4\cdot NH\cdot C_{10}H_7)$ is formed. It is readily soluble in aniline, more sparingly in acetone, acetic acid, and alcohol, and separates according to the nature of the solvent and the concentration, as a bluish-violet or dark brownish-red powder, and was once obtained from acetone in crystals having a bronze lustre. It is also readily converted into a leuco-base.

Carbazole-blue probably has a similar constitution, but it was not found possible to obtain this compound sufficiently pure for analysis.

H. G. C.

Derivatives of α- and β-Naphthylglycin. By C. A. Bischoff and A. Hausdorfer (*Ber.*, 23, 2003—2009).—As already stated by Bischoff and Nastvogel, α-naphthylglycin cannot by simple heating be converted into α-dinaphthyl-αγ-diketopiperazine,

$$C_{10}H\text{-}N{<}\begin{matrix}CH_2\cdot CO\\ CO\cdot CH_2\end{matrix}{>}N\cdot C_{10}H\,,$$

(Abstr., 1889, 1015). The latter may, however, be obtained by heating a mixture of α-naphthylglycin and acetic anhydride in molecular proportion. It crystallises from a mixture of alcohol and acetic acid in lustrous plates melting at 275°, and is identical with the compound obtained by Abenius (this vol., p. 269) from chloracetonaphthalide. By the action of alkalis, the ring appears to be split, and the acid $C_{10}H_7\cdot NH\cdot CH_2\cdot CO\cdot N(C_{10}H_7)\cdot CH_2\cdot COOH$ formed.

α-Naphthylimidodiacetic acid, $C_{10}H_7\cdot N(CH_2\cdot COOH)_2$, is obtained by heating together α-naphthylglycin, monacetonaphthalide, and chloracetic acid, and crystallises from benzene with benzene of crystallisation, which is given off at 100°. Both the acid containing benzene and that dried at 100° melt at 133—133·5°. It is readily soluble in alcohol, chloroform, and acetic acid, sparingly in benzene and light petroleum. By the action of α-naphthylamine, it is converted into the *mono-* and *di-naphthalide* melting at 197—199° and 200—202° respectively.

β-Dinaphthyl-αγ-diketopiperazine is obtained, unlike the α-compound, by simply heating β-naphthylglycin in a current of hydrogen at 220°. It forms colourless, very lustrous plates, which only decompose above 360°, and are insoluble in the ordinary solvents. As with the α-compound, the ring appears to be split with alkalis. The same piperazine may be obtained by dissolving β-naphthylglycinnaphthalide in amyl alcohol, adding first the theoretical quantity of sodium, then the corresponding quantity of ethyl chloracetate, and boiling for several hours.

When β-naphthylamine, chloracetic acid, and sodium acetate are heated together, the chief product is the extremely stable β-naphthylamine salt of β-naphthylglycin, already described by Jolles (Abstr., 1889, 1199). If, however, β-naphthylglycin be neutralised with sodium carbonate in aqueous solution, and the requisite quantity of chloracetic acid, also in aqueous solution, gradually added with constant stirring, and the whole heated at 130—150°, *β-naphthylimidodiacetic acid*, $C_{10}H_7\cdot N(CH_2\cdot COOH)_2$, is formed. This separates as a white precipitate which decomposes at 182°, and is soluble in alkalis, alcohol, and acetone, sparingly in ether and chloroform, and insoluble in benzene and light petroleum.

H. G. C.

Derivatives of Lapachic Acid. By E. Paternò and G. Minunni (*Gazz.*, **19**, 601—623).—Paternò (Abstr., 1883, 210) found that when the red solution of an alkaline lapachate is treated with zinc-dust it becomes bright yellow, and on precipitation with hydrochloric acid yields a compound crystallising in colourless needles, which rapidly absorb oxygen and pass into lapachic acid. The authors find that even when all the operations are conducted in an atmosphere of hydrogen, the compound precipitated by hydrochloric acid, although white at first, rapidly darkens; the ethereal solution, moreover, on distillation yields a blackish oil, the aqueous extract of which deposits on cooling the unstable needles mentioned. The composition of this substance was determined by drying the original ethereal solution with calcium chloride, and acetylating it in a current of carbonic anhydride. The product is the triacetyl-derivative of a trihydroxyamylenenaphthalene, $C_{15}H_{13}(OAc)_3$; it crystallises from alcohol in long, colourless prisms, which melt at 139°, and are insoluble in water. It slowly dissolves in a dilute solution of potash, and hydrochloric acid reprecipitates lapachic acid from the solution.

Diacetylhydroisolapachone and Isolapachone.—When lapachic acid is heated with excess of sodium acetate and acetic anhydride, the diacetyl-derivative of an unstable quinol, $C_{15}H_{14}O(OAc)_2$, crystallises out in needles melting at 131—132°; on carefully hydrolysing this substance in a reducing atmosphere, and dissolving the product in ether, a colourless solution is obtained which rapidly oxidises on desiccation, and is converted into a quinone isomeric with lapachic acid and lapachone. The authors term this substance *isolapachone*. It crystallises in orange needles melting at 140—141°, and it may be reconverted into the preceding diacetyl-derivative by reduction and acetylation.

Diacetylhydrolapachone.—When an alcoholic solution of lapachone is reduced with an equal weight of sodium, and the precipitate formed by hydrochloric acid taken up with ether in a reducing atmosphere, the solution leaves on distillation a black oil which partly resinifies on standing; if the solution is directly acetylated, a diacetyl-derivative, $C_{15}H_{14}(OAc)_2$, is formed, which crystallises from alcohol in colourless cubes, melts at 161°, and is slightly soluble in cold alcohol, ether, &c.

Lapachic acid does not yield an oxime or hydrazone when treated by ordinary methods; an *oxime*, $C_{15}H_{14}O_2{:}NOH$, crystallising in greenish-yellow prisms may, however, be obtained by treating a cold alcoholic solution of lapachic acid with twice its weight of hydroxylamine hydrochloride and an equivalent quantity of sodium carbonate, the mixture being allowed to remain for three or four days. The *hydrazone*, $C_{15}H_{14}O_2{:}N_2PhH$, may be obtained by dissolving the acid directly in phenylhydrazine, heating to 120°, and allowing it to remain for a few days. It crystallises from alcohol in tufts of brick-red needles which melt at 108—109°, and are only slightly soluble in ordinary solvents.

Lapachone readily forms a *monoxime*, which crystallises from alcohol in silky, orange-yellow, pointed prisms, and melts at 168·5—169·5°. The *benzoyl-derivative*, $C_{15}H_{14}O{:}NOBz$, forms golden-yellow plates, melting at 180—181°. On reducing the oxime with tin and hydrochloric acid, the solution successively acquires a brown and a deep-violet colour, and contains lapachone together with a substance crystallising in yellow needles and melting at about 110°. The *hydrazone* forms orange-yellow needles, which melt at 188—189° and dissolve sparingly in alcohol, ether, or acetic acid, and moderately in benzene. On reducing an acetic acid solution with sodium amalgam, a blood-red solution is obtained, but no definite compound could be isolated.

The substance obtained by Paternò in red crystals (blue by transmitted light) by treating lapachone with acetic anhydride and sodium acetate, has the composition $C_{30}H_{26}O_5$, and is probably an anhydride of lapachone or of one of its isomerides; it is a very stable compound, and is generally resinified by the reagents which have any action on it. The constitution of the above compounds is discussed at some length; the authors consider that lapachic acid, lapachone, and isolapachone are probably derivatives of α-naphthaquinone, and have respectively the structure represented by the formulæ I, II, III.

Determinations of the molecular weights of nearly all the substances described were made by Raoult's method. S. B. A. A.

β-Dinaphthylcarbamide Chloride and β-Tetranaphthylcarbamide. By B. Kühn and N. Landau (*Ber.*, **23**, 2161—2162).—A reply to Kym (this vol., p. 993), in which the authors give details of their experiments on the interaction of carbonyl chloride and β-dinaphthylamine in benzene-toluene solution at the ordinary temperature (compare Kym, this vol., p. 633, and Kühn and Landau, this vol., p. 634).

β-Tetranaphthylcarbamide melts at 287—288°, not at 167—169°, as previously stated. F. S. K.

Dinaphthyl Sulphides and Dinaphthylsulphones. By F. Krafft (*Ber.*, **23**, 2364—2369; compare Abstr., 1889, 715).—ββ-Dinaphthylsulphone, $(C_{10}H_7)_2SO_2$, is prepared by oxidising ββ-dinaphthyl sulphide (m. p. 151°) with a mixture of glacial acetic acid and potassium dichromate dissolved in dilute sulphuric acid; it is identical with the compound obtained by Stenhouse and Groves from naphthalene and sulphuric acid (compare this journal, 1876 ii, 517). It may be distilled under reduced pressure without undergoing decomposition. *αα-Dinaphthyl sulphoxide*, $(C_{10}H_7)_2SO$, is formed by gently warming αα-dinaphthyl sulphide (3 parts), dissolved in glacial acetic acid (250 parts), with a solution of potassium dichromate (3 parts) in dilute (1 : 3) sulphuric acid (20 parts) and glacial acetic acid (100 parts); it is deposited from alcohol in white crystals, melting at 164·5°, and is probably identical with the sulphoxide

(m. p. 162°) obtained by Ekstrand from naphthylene dinaphthyl sulphoxide (compare Abstr., 1885, 170), and also with the "sulphone" (m. p. 166°) prepared by Leükart from *αα*-dinaphthyl sulphide (compare Abstr., this vol., p. 603). *αα-Dinaphthylsulphone*, $(C_{10}H_7)_2SO_2$, is formed by oxidation of the corresponding sulphide (1 part) dissolved in glacial acetic acid (100 parts), with potassium dichromate (3 parts), dilute (1 : 3) sulphuric acid (15 parts), and glacial acetic acid (20 parts); it crystallises from alcohol, and melts at 187°. *αβ-Dinaphthyl sulphide*, $(C_{10}H_7)_2S$, is obtained by heating an intimate mixture of equivalent parts of *α*-bromonaphthalene and the lead salt of *β*-naphthyl hydrogen sulphide at 200—240° for about six hours; the product is treated with carbon bisulphide after purification; it crystallises from dilute alcohol in lustrous plates which melt at 60—61°, and boil at 290—291° under pressure of 15 mm. *αβ*-Dinaphthylsulphone, $(C_{10}H_7)_2SO_2$, is prepared by the oxidation of the sulphide; it melts at 122·5—123°, and is identical with the "*α*-sulphone" obtained by Stenhouse and Groves (*loc. cit.*). J. B. T.

Chrysene. By E. Bamberger and C. Burgdorf (*Ber.*, 23, 2433—2446; compare Abstr., 1885, 1069).—The close analogy which has been shown to exist between the derivatives of phenanthraquinone and chrysoquinone has led the authors to endeavour to prepare the two unknown acids in the chrysene series, corresponding with diphenic acid and phenylbenzoic acid respectively. The diphenic acid analogue could not be obtained, as the oxidising agents employed invariably attacked the naphthalene nucleus as well as the carbonyl-group. Chrysoquinone is prepared by boiling chrysene (50 grams) with glacial acetic acid (1 kilo.) and gradually adding chromic anhydride (100 grams) dissolved in glacial acetic acid (1 kilo.); the operation should last 8—10 hours: the yield is 96—97 per cent. of the theory. Potassium permanganate acts more readily on chrysene, phthalic acid being the sole product. On distilling chrysoquinone over soda-lime, a complicated mixture was obtained, from which no definite compound, except chrysene, could be isolated. This result is opposed to the observations of Graebe, and of E. Schmidt, who prepared phenylnaphthalene (m. p. 104—105°) in this manner. The preparation of chrysoketone,  $\begin{matrix}C_6H_4\\|\\C_{10}H_6\end{matrix}\!>CO$, has already been described (*loc. cit.*); it melts at 132·5°, not at 130° as stated, and crystallises from alcohol, on the addition of water, in thin, lustrous, golden needles; by fusion and subsequent cooling, thick, orange-red prisms are obtained; both forms belong to the rhombic system, the difference in appearance is due to pleichroism.

On heating chrysoquinone with 10 parts of potassium hydroxide at 225 - 230° for an hour, an acid is formed, crystallising from benzene in silvery-white, lustrous plates which melt at 186·5°; it readily dissolves in all the ordinary solvents except water, and is not acted on by dilute sulphuric acid at 200°. It yields chrysoketone by treatment with concentrated sulphuric acid. This compound, which the authors call *chrysenic acid*, is either naphthylbenzoic acid, $C_{10}H_7{\cdot}C_6H_4{\cdot}COOH$, or phenylnaphthoic acid, $C_{10}H_6Ph{\cdot}COOH$; it is also obtained by the fusion of chrysoketone with potassium hydroxide. All attempts to prepare the corresponding hydrocarbon were unsuccessful. The barium salt, $C_{34}H_{22}O_4Ba + H_2O$, crystallises in stellate clusters of silvery, lustrous needles.

A second acid, *isochrysenic acid*, is formed by boiling chrysoketone with alcoholic potash for 8—10 hours, it is very soluble and extremely difficult to purify; on distillation with calcium hydroxide, it yields a hydrocarbon which crystallises from alcohol in lustrous, silvery-white plates melting at 181·5°.

Nitrochrysene may be readily prepared by warming a mixture of finely-divided chrysene (10 grams) with 10 parts of glacial acetic acid, and nitric acid (4·5 grams) of sp. gr. 1·415, for several hours on the water-bath. *Amidochrysene*, $C_{18}H_{11}{\cdot}NH_2$, is obtained by the action of tin and hydrochloric acid on a boiling glacial acetic acid solution of nitrochrysene; it is precipitated by alkalis from its salts as a white, crystalline powder melting at 199°. It quickly becomes coloured on exposure to air, and its solutions exhibit an intense blue-violet fluorescence. A dark-red dye is formed by the action of diazobenzenesulphonic acid on amidochrysene. The *platinochloride* is a yellow, crystalline substance. The *sulphate* and *hydrochloride* are very sparingly soluble.

J. B. T.

Camphene Glycol and Tetrahydric Alcohol from Limonene.

By G. Wagner (*Ber.*, 23, 2307—2318).—It is first stated that a substance containing an ethylene linking loses this when oxidised with alkaline permanganate and adds on two hydroxyls, and this principle is then used to determine the existence of ethylene bonds in certain terpenes.

Camphene contains one ethylene linking, for it takes up two hydroxyl-groups and forms a glycol. A solution of camphene in the smallest possible quantity of benzene was poured into a large quantity of 1 per cent. permanganate solution and shaken until the pink colour disappeared. The mixture was then allowed to remain, and the clear alkaline liquid finally drawn off from the brown precipitate in a current of carbonic anhydride, and the residue washed with water. This was twice repeated. The alkaline solutions were saturated with carbonic anhydride and repeatedly extracted with benzene. The benzene was evaporated, the residue saturated with potash and extracted with ether, the ether extract evaporated, and the residue recrystallised from benzene. It was *camphene glycol*, $C_{10}H_{16}(OH)_2$, and formed prismatic needles of the monoclinic system, which sublime above 100° and melt, seemingly with slight decomposition, at 192°. It dissolves easily in ether, alcohol, carbon bisulphide, and chloroform, less easily in benzene. With acetic anhydride, it yields only a small quantity of a diacetyl-derivative, secondary reactions apparently taking place. It readily loses water, especially when heated with dilute hydrochloric acid; a solid substance, apparently isomeric with camphor, $C_{10}H_{16}O$, distils over with water, and when allowed to remain liquefies and becomes acid. It smells like camphor, but has marked aldehydic properties, reducing silver nitrate, &c. Its constitution is at present undetermined.

Limonene contains two ethylene linkings, for it takes up four hydroxyl-groups. A 1 per cent. permanganate solution was run slowly into a mixture of carvene and water, the mixture being continually shaken, and finally allowed to remain. The solution was filtered, the filtrate extracted with benzene, and distilled with water after the addition of some magnesium sulphate to prevent decomposition. The residue was concentrated and extracted with ether. A substance was thus obtained which, after recrystallisation from benzene, formed fine, brilliant, interwoven needles melting at 191·5—192°. It is *limonetrol*, a tetrahydric glycol, $C_{10}H_{16}(OH)_4$. It dissolves easily in water, and has a faintly sweet taste.

The paper contains some general remarks on the oxidation of saturated and unsaturated compounds, and attention is called to the fact that benzene-derivatives, when oxidised, behave like saturated, and not like unsaturated, fatty derivatives. C. F. B.

Terpenes and Ethereal Oils. By O. Wallach (*Annalen*, **258**, 319—339; compare this vol., p. 169).—Further experiments have shown that cineolic acid (Abstr., 1888, 1205) has the composition $C_{10}H_{16}O_5$ previously assigned to it. The *methyl* salt, $C_8H_{14}O(COOMe)_2$, melts at 31°. The *anhydride*, $C_{10}H_{14}O_4$, is obtained when the acid is warmed with acetic anhydride; this crystallises from a mixture of benzene and light petroleum in long needles, melts at 77—78°, and boils at 157° under a pressure of 12—13 mm.; it is very soluble in chloroform and benzene, and is reconverted into the acid by boiling water.

When cineolic acid is subjected to dry distillation, it is decomposed into carbonic anhydride, water, a monocarboxylic acid of the composition $C_9H_{16}O_3$, and a neutral liquid; cineolic anhydride under the same conditions is decomposed quantitatively into carbonic oxide, carbonic anhydride, and the same neutral compound as that obtained from the acid. The neutral compound is separated from small quantities of anhydride by distillation with steam; it boils at 173—174° and has the molecular formula $C_8H_{14}O$, as was proved by analysis and by a vapour density determination. It has a penetrating odour very like that of amyl acetate, its sp. gr. is 0·8530 at 20°, and its refractive power is $n_D = 1·44003$. It combines readily with bromine and with halogen acids, and is decomposed by potassium permanganate in the cold, yielding carbonic anhydride and an unstable acid, but it does not decolorise a sulphurous acid solution of magenta; it combines with phenylhydrazine yielding an oil, and it forms a crystalline compound with sodium hydrogen sulphite. Its molecular refraction is 38·93, calculated for the formula $C_8H_{14}O$, from the data given above; employing Conrady's values, the molecular refraction of $C_8H_{14}O''|^{-} = 38·72$, whereas that of $C_8H_{14}O'|^{-} = 37·9$ and of $C_8H_{14}O'|^{=} = 39·65$.

Metahydroxylene, C_8H_{12}, is obtained, together with a liquid boiling at 280—285°, which seems to be a polymeride thereof, when the compound of the composition $C_8H_{14}O$ is heated with zinc chloride at 90—95°; it is a liquid of sp. gr. 0·8275 at 20°, boils at 132—134°, and has an odour of xylene; its refractive power is $n_D = 1·4675$. It resembles the terpenes in many respects, and like them combines readily with halogens and halogen acids; on oxidation with dilute nitric acid and potassium permanganate consecutively, it yields an acid which seems to be isophthalic acid. When carefully treated with ice-cold concentrated nitric acid, it yields nitrometaxylene, which was identified by converting it into metaxylidine; *diacetylmetaxylidine*, $C_6H_3Me_2{\cdot}NAc_2$, separates from light petroleum in well-defined crystals, melts at 60°, and is readily soluble in benzene. Metahydroxylene can also be converted into dinitrometaxylene (m. p 90—91°) and trinitrometaxylene (m. p. 180—182°) by treating it with a mixture of concentrated sulphuric acid and nitric acid, first in the cold and then at 100°; the dinitro-compound was identified by reducing it to nitroxylidine (m. p. 123°) and converting the latter into its acetyl-derivative (m. p. 115—116°).

The formation of metaxylene from cineole in the manner described above might be considered as evidence in favour of the view that cineole, and the terpenes generally, contain two side-chains in the meta-position, especially as metaxylene has been previously obtained from pinene by Tilden (Trans., 1884, 416). The following arguments show, however, that this is not the case, and that the above series of reactions can be best explained by assuming that cineole has the constitution  $\mathrm{CMe}\left\langle\begin{matrix}\mathrm{CH_2{\cdot}CH_2}\\ \mathrm{O}\\ \mathrm{CH_2{\cdot}CH_2}\end{matrix}\right\rangle\mathrm{CPr^{\beta}}$ assigned to it by Richter and accepted by Brühl. For, granting that cineole has this constitution and that its oxidation to cineolic acid is a reaction analogous to that which is generally assumed to take place in the formation of camphoric acid from camphor, the constitution of cineolic acid may be represented by the formula  $\begin{matrix}\mathrm{CH_2{\cdot}CPr^{\beta}(COOH)}\\ |\\ \mathrm{CH_2{\cdot}CMe(COOH)}\end{matrix}\Big\rangle\mathrm{O}$; this view would explain the formation of an anhydride and the conversion of cineolic acid into a monocarboxylic acid with evolution of carbonic anhydride. An anhydride of the constitution  $\left|\begin{matrix}\mathrm{CH_2{\cdot}CPr^{\beta}{\cdot}CO}\\ \mathrm{O}\\ \mathrm{CH_2{\cdot}CMe{\cdot}CO}\end{matrix}\right\rangle\mathrm{O}$ might be decomposed into carbonic oxide, carbonic anhydride, and an unstable compound of the constitution  $\begin{matrix}\mathrm{CH_2{\cdot}CPr^{\beta}}\\ |\quad\ |\\ \mathrm{CH_2{\cdot}CMe}\end{matrix}\Big\rangle\mathrm{O}$, which might then undergo an intramolecular change, analogous to that which is supposed to take place in the formation of a pinacoline, and be converted into a ketone of the constitution $\mathrm{CHPr^{\beta}{:}CH{\cdot}CH_2{\cdot}COMe}$. A ketone of this nature would probably have the properties possessed by the compound $C_8H_{14}O$, and it might be easily converted into metahydroxylene by the elimination of 1 mol. H_2O. The synthesis of the compound $C_8H_{14}O$ from a ketone of the above constitution will be attempted.

F. S. K.

Pinene. By O. WALLACH (*Annalen*, 258, 343—347).—It has been previously shown (Abstr., 1889, 1069) that pinene nitrosochloride is decomposed by aniline in accordance with the equation

$C_{10}H_{16}{\cdot}NOCl + 2C_6H_5{\cdot}NH_2 = H_2O + HCl + N_2Ph{\cdot}C_6H_4{\cdot}NH_2 + C_{10}H_{16}$. The hydrocarbon obtained in this way has now been found to be chemically pure, inactive pinene; it boils at 155—156°, its sp. gr. is 0·858 at 20°, and its refractive power $n_D = 1{\cdot}46553$ at 21°. It remains inactive even when treated with hydrogen chloride, a fact which is more noteworthy since the inactive pinene obtained in other ways becomes lævorotatory under these conditions (compare Abstr., 1889, 1071) and probably consists, therefore, of equal parts of dextro- and lævo-pinene. Inactive pinene combines readily with nitrosyl chloride yielding the same products as the active modifications, namely, a crystalline nitrosochloride and pinole (compare Wallach and Otto, this vol., p. 169).

A liquid base of the composition $C_{10}H_{15}{\cdot}NH_2$ is obtained when nitrosopinene is treated with zinc and glacial acetic acid or with a mixture of hydriodic acid and glacial acetic acid; it boils at 207—208° (at 98—99° under a pressure of 22 to 23 mm.) and has an odour recalling that of borneol. The hydrochloride melts at 221—222°, and the benzoyl-derivative at 116°; the sulphate crystallises well. The investigation of this base is being continued.

F. S. K.

So-called Massoyene. By O. Wallach (*Annalen*, 258, 340—343).—The author has examined a sample of massoy-bark oil obtained from the same source as the oil investigated by Woy (this vol., p. 638); he finds that Woy's "massoyene" is not a new terpene but a mixture of various compounds, from which he isolated pinene. F. S. K.

Constituents of the Bark of Nerium oleander. By E. Pieszczek (*Arch. Pharm.*, 228, 352—361).—By treating the bark with light petroleum, a liquid fat and a wax-like crystalline compound were extracted, which will be described later. The bark was then extracted with alcohol, the solution distilled to remove most of the alcohol, and filtered to remove a remnant of fat and a caoutchouc-like deposit. After several days, nodular aggregates of almost colourless, microscopic crystals formed. On recrystallisation from dilute alcohol, the substance was obtained as an almost colourless, soft, crystalline mass, insoluble in water, light petroleum, ether, and chloroform, easily soluble in alcohol. On warming with dilute hydrochloric acid, it gives the glucose reaction with copper solution, so that it is a glucoside. The alcoholic solution is not precipitated by tannin, platinic chloride, mercuric chloride, iodised potassium iodide, Nessler's reagent, lead acetate, or ammonia. It melts at 171°, then decomposes with separation of carbon, and burns with a smoky flame. It dissolves in concentrated sulphuric acid to a reddish-brown solution, not essentially changed by bromine vapour. *Rosaginin* is proposed as the name of the compound. It is exceedingly poisonous, resembling strychnine in its action. The mother liquor from the rosaginin contained *neriin*, a glucoside identical with the compound obtained by Schmiedeberg from the leaves of the same plant.

Small quantities of a volatile oil of disagreeable odour and a crystalline, fluorescent compound were also obtained. J. T.

Myrrh. By O. Köhler (*Arch. Pharm.*, **228**, 291—313).—The raw material consists of gum, resin, and an ethereal oil. The portion soluble in water, but insoluble in alcohol, amounting to 57 to 59 per cent. of the whole, is a gum of the carbohydrate formula, $C_6H_{10}O_5$, as shown by analysis and the formation of levulinic acid when heated with hydrochloric acid. The part soluble in alcohol is a mixture of several resins, the greater portion of which is a soft resin, $C_{26}H_{34}O_5$, containing three displaceable hydroxyl-groups, and is soluble in ether. There are also present two bibasic acids, $C_{13}H_{16}O_8$ and $C_{26}H_{32}O_9$ respectively. The ethereal oil, 7 to 8 per cent. of the whole, was found to consist mainly of the compound $C_{10}H_{14}O$. By doubling the formula of one of the acids, the three resinous constituents are seen to have each 26 atoms of carbon in their molecule, and the chief difference between them is probably due to oxidation. J. T.

Damascenine from Nigella damascena, L. By A. Schneider (*J. Pharm.* [5], **22**, 58—61; from *Pharm. Centralhalle*, **21**, 173).—The crushed seeds of this plant are extracted with benzene, this is agitated with dilute hydrochloric acid, and the alkaloïd is precipitated by excess of sodium hydroxide and filtered off. A further crop is obtained by treating the filtrate with chloroform, extracting this with dilute hydrochloric acid, and precipitating with sodium hydroxide The product is purified by dissolving it in absolute alcohol and evaporating over sulphuric acid in a vacuum, when a thick, brownish-yellow, fluorescent liquid is left which gives large crystals of an alkaloïd, *damascenine*, when placed in a freezing mixture. These crystals are dried between blotting-paper in the cold, as the heat of the hand melts them. The yield is about 0 1 per cent. *Nigella sativa* and *N. arvensis* do not appear to contain the alkaloid. The crystals are slightly yellow, with a bluish fluorescence and a narcotic odour; their reaction is alkaline; they melt at 27° and recrystallise on cooling. The fused compound forms a yellowish, feebly fluorescent oil of sp. gr. 1·01, and gives a greasy stain on paper which disappears on heating. It boils at 168°, but emits vapours at the ordinary temperature. The alkaloid is insoluble in cold water, slightly soluble in hot water, easily soluble in alcohol, chloroform, methyl alcohol, carbon bisulphide, benzene, light petroleum, and in the fatty oils. All these solutions have a blue fluorescence, which, in the case of benzene, is perceptible with 1 : 200,000. Damascenine dissolves readily in dilute acids. These solutions, which are not fluorescent, yield amorphous precipitates with the ordinary reagents of the alkaloids. A characteristic reaction is the beautiful reddish-violet colour produced by long contact of the alkaloid with excess of concentrated nitric acid. *Damascenine hydrochloride* is obtained by adding concentrated hydrochloric acid to a solution of the alkaloid in absolute alcohol, and then adding ether until the precipitate formed just ceases to dissolve on shaking. On standing, the salt crystallises out. The crystals melt at 121°. The nitrate and sulphate are prepared in a similar manner. Analysis of the alkaloïd points to the formula $C_{20}H_{25}NO_6$. J. T.

Ferrocyanides of the Alkaloïds. By H. BECKURTS (*Arch. Pharm.*, 228, 347—352).—According as the decomposition of the alkaloïd salts by potassium ferrocyanide takes place in neutral or acid aqueous solutions, the resulting alkaloïd ferrocyanide is normal or acid. The acid ferrocyanides are prepared by dissolving the alkaloid in concentrated hydrochloric acid, and adding the least possible excess of a concentrated aqueous solution of potassium ferrocyanide; the resulting precipitate is washed and dried. The following acid ferrocyanides were produced. *Atropine* salt, $C_{17}H_{23}NO_3,H_4FeC_6N_6$; amorphous powder, soluble in water and potassium ferrocyanide solution, insoluble in alcohol and ether. *Quinine* salt, $C_{20}H_{24}N_2O_2,H_4FeC_6N_6$; greenish, amorphous powder, soluble in much water and in potassium ferrocyanide solution, insoluble in alcohol, ether, and chloroform. *Quinidine* salt; yellowish-white, crystalline powder, sparingly soluble in water, insoluble in chloroform, alcohol, and ether. *Cinchonine* salt; orange-yellow, crystalline powder, sparingly soluble in water, insoluble in alcohol, ether, and chloroform. *Cinchonidine* salt; reddish-yellow, crystalline powder, sparingly soluble in water. *Cocaine* salt,

$$(C_{17}H_{21}NO_4)_2,H_4FeC_6N_6;$$

white, amorphous powder, easily soluble in excess of potassium ferrocyanide solution, sparingly soluble in water, insoluble in alcohol and ether. *Coniine* salt; amorphous, white powder. *Hydrastine* salt; white, amorphous, sparingly soluble powder. *Morphine* salt; white, crystalline powder, easily soluble in water; becomes pale-blue in the air. *Narceine* salt; bluish-white, crystalline powder, somewhat sparingly soluble in water. *Narcotine* salt; bluish-white, crystalline, voluminous powder, easily soluble in water. *Pilocarpine* salt; white, crystalline powder, easily soluble in water. *Sparteine* salt; white, crystalline powder, easily soluble in water. *Strychnine* salt; white, crystalline powder with a bluish shade, insoluble in cold water and alcohol, decomposed by hot water with separation of hydrogen ferrocyanide. *Brucine* salt; white, microscopic, prismatic crystals which quickly turn blue in the air; dilute solutions gradually deposit large, white prisms. J. T.

Reduction-products of Quinoline. By E. BAMBERGER and F. LENGFELD (*Ber.*, 23, 1138—1158).—When tetrahydroquinoline hydrochloride (3 grams) is heated with hydriodic acid (sp. gr. = 1·9) (16 grams) and red phosphorus (1·75 grams) at 230° for 3—4 hours, a product is obtained consisting of 55 per cent. of decahydroquinoline and 8 per cent. of hexahydroquinoline, together with about 0·25 per cent. of a hydrocarbon, possibly propylhexamethylene, and a third base which has not yet been examined and is not volatile with steam. To separate it into its constituents, the product is rendered alkaline and submitted to steam distillation until the distillate comes over neutral and gives no colour with potassium dichromate or ferric chloride in acid solution. The distillate is acidified with hydrochloric acid, extracted with ether to remove the insoluble hydrocarbon, evaporated to a small bulk, rendered alkaline, and the separated bases dissolved in ether. The ethereal solution, on evaporation, leaves an oil from which the decahydro-base is separated by extraction with very weak acetic acid, the hexahydro-base remaining undissolved.

Decahydroquinoline, C_9NH_{17}, is best purified by distillation under the ordinary pressure. It crystallises from water or light petroleum in thin, colourless prisms, melts at 48·2—48·5°, boils at 204° (therm. in vapour) under 714 mm. pressure, has a very intense basic odour extremely like that of coniine, and readily absorbs carbonic anhydride from the air. It is very volatile even with ether vapour, sublimes at the ordinary temperature in lustrous aggregates of needles, is not only very soluble in the ordinary organic solvents, but also in water, dissolves sparingly in alkalis, gives no colour reactions with potassium dichromate, ferric chloride, or diazo-compounds, and in physiological action resembles piperidine. Its aqueous solution has a strong alkaline reaction. The salts, which are anhydrous, crystallise well, and for the most part are readily soluble in water forming neutral solutions. The *hydrochloride*, C_9NH_{17},HCl, crystallises in small, colourless, lustrous, rhombic tables, melts at 275·5—276°, and is very soluble in alcohol and water; the *aurochloride*, $C_9NH_{17},HAuCl_4$, forms small, golden-yellow needles, melts at 96°, and is soluble in alcohol and chloroform, sparingly soluble in cold water, and insoluble in benzene and light petroleum; the *platinochloride*, $(C_9NH_{17})_2,H_2PtCl_6$, crystallises in lustrous, orange-red, thick prisms, melts at 207—207·5° with decomposition, and is readily soluble in water, insoluble in alcohol, chloroform, benzene, &c.; the *hydriodide*, C_9NH_{17},HI, forms long, silky needles, melts at 253°, and is somewhat less soluble in water than the hydrochloride; the *hydrogen sulphate* crystallises in very soluble, flat needles, and the *picrate* in yellow needles. The *acetyl*-derivative, $C_9NH_{16}Ac$, is a colourless, viscid oil, dissolves readily in the ordinary solvents, including water, and does not combine with bromine; the *benzoyl*-derivative, $C_9NH_{16}Bz$, crystallises in lustrous, white needles, melts at 44°, and is readily soluble in the ordinary organic solvents, sparingly soluble in water. The *nitrosamine*, $C_9NH_{16}\cdot NO$, is a yellow, viscid liquid which dissolves readily in concentrated acids and the ordinary organic solvents, sparingly in water, gives a grass-green colour when mixed with phenol and sulphuric acid and subsequently treated with alkali, and regenerates the base when hydrogen chloride is passed into its ethereal solution. The *diazoamido*-compound, $C_9NH_{16}\cdot N_2\cdot Ph$, crystallises from ether in flat, lustrous tables resembling crystals of alloxan, from alcohol in stellate groups of silver-white needles, melts at 78·6°, dissolves readily in the ordinary organic solvents, and yields phenol and decahydroquinoline with the evolution of nitrogen when warmed with mineral acids. The *phenylthiocarbamide*, $C_9NH_{16}\cdot CS\cdot NHPh$, crystallises from chloroform in beautiful, rhombic tables, melts at 134·5°, and is readily soluble in chloroform, alcohol, and benzene, sparingly soluble in ether, and almost insoluble in water and light petroleum; the *phenylcarbamide*, $C_9NH_{16}\cdot CO\cdot NHPh$, crystallises from alcohol in lustrous, silvery needles, melts at 148°, and in solubility resembles the thio-compound. The *decahydroquinolyldithiocarbamate*, $C_9NH_{16}\cdot CS\cdot SH,C_9NH_{17}$, forms lustrous, white, flat needles, melts at 120°, dissolves readily in alcohol, chloroform, benzene, and hot water, sparingly in ether and cold water, is not decomposed by prolonged boiling with alcohol, and yields the *thiuramsulphide*, $C_9NH_{16}\cdot CS\cdot S_2\cdot SC\cdot C_9NH_{16}$, on treatment in alcoholic solution with iodine.

Hexahydroquinoline, C_9NH_{13}, is a colourless, viscid liquid, boiling at 226° under 720 mm. pressure. It has a neutral reaction, resembles quinoline in odour, is readily soluble in the ordinary organic solvents, sparingly soluble in water, gives brown flocks when treated with potassium dichromate or ferric chloride in acid solution, and is converted into a bright-red azo-dye by the action of diazobenzenesulphonic acid. In physiological action it resembles quinoline more closely than decahydroquinoline. The *hydrochloride*, C_9NH_{13},HCl, forms white, silky needles, melts at 170°, and is readily soluble in alcohol and water, sparingly soluble in hydrochloric acid; the *hydrobromide* crystallises in long, silky needles.

The hydrocarbon formed in the reduction of tetrahydroquinoline, and provisionally regarded as *propylhexamethylene*, is a colourless, mobile liquid of pleasant aromatic odour, boiling at 146—148° (therm. in vapour) under 720 mm. pressure. W. P. W.

Bromo-derivatives of Quinoline. By A. CLAUS and A. WELTER (*J. pr. Chem.* [2], **42**, 233—247; see also this vol., p. 173).—1 : 4′-*Dibromoquinoline.*—To prepare this compound, 1-bromoquinoline is converted by Claus and Tornier's method (Abstr., 1888, 163) into the additive compound, C_9NH_6Br,HBr,Br_2, a red, crystalline mass which melts at 70° with decomposition. On heating this compound in a retort at 200° for 4—6 hours, a mixture of hydrobromides and free bromoquinolines sublimes, which is treated with soda and distilled in a current of steam, and the 1 : 4′-dibromoquinoline separated from the solution of the distillate in hydrochloric acid by fractional precipitation with water. On recrystallisation from alcohol, it forms silky needles which melt at 101—102° (uncorr.), and are readily soluble in ether, alcohol, and chloroform.

1 : 4′-Dibromoquinoline may also be obtained from 1-nitroquinoline by acting on it with bromine in hydrobromic acid solution, and heating the additive product in a retort at 200°. Its *hydrochloride*, $C_9NH_5Br_2,HCl$, forms large, well-developed prisms which melt at 141—142°, are not stable in the air, and are decomposed by alcohol and water. The *sulphate* melts at 206°, the *chromate* at 158° with decomposition, whilst the *platinochloride* remains unaltered at 280°, but blackens at a higher temperature.

Nitro-1 : 4′-*dibromoquinoline*, $C_9NH_4Br_2\cdot NO_2$, is obtained by the action of a mixture of sulphuric and nitric acids on the foregoing compound. It is very sparingly soluble in alcohol, readily in ether, chloroform, and concentrated mineral acids, crystallising out unaltered from the latter. Its *platinochloride* forms short, six-sided prisms. On reduction, it yields *amido* 1 : 4′-*dibromoquinoline*, $C_9NH_4Br_2\cdot NH_2$, which crystallises in small, colourless needles melting about 170°, readily soluble in alcohol, ether, chloroform, and even in hot water. It assumes an intense red coloration when acted on by hydrogen chloride. The *hydrochloride* crystallises in long, red needles melting at 214—215°, and the *platinochloride* in beautiful, yellow needles.

1 : 4 : 4′-*Tribromoquinoline*, $C_9NH_4Br_3$.—This compound, which was formerly described as γ-tribromoquinoline, is the most frequent product of the further bromination of quinoline. Its constitution has been ascertained by its synthetical formation, the manner of which will be described in a later paper. It is best prepared by heating 4′-bromoquinoline with bromine and water at 130—150°, substitution-products being thus almost exclusively formed. To isolate the 1 : 4 : 4′-tribromoquinoline, the product is distilled in a current of steam, and the different distillates fractionally precipitated from their hydrochloric acid solution by water; the higher brominated products first separating, and then the tribromo-compound. On recrystallisation from alcohol, it melts constantly at 167° (uncorr.), and is readily soluble in ether and chloroform, and in concentrated acids. If it be dissolved in concentrated nitric acid, reprecipitated by water, and again recrystallised from alcohol, it forms long, silky needles melting at 169—170°. It volatilises with difficulty in a current of steam, sublimes without decomposition, and is not acted on by methyl iodide at 140°. Its *hydrochloride* forms silvery scales which are decomposed by water, alcohol, and dilute acids. The *platinochloride* has also been prepared. On oxidation, the base is completely converted into bromine, carbonic anhydride, nitrogen, and water; it is unaltered by dilute boiling aqueous potash. Alcoholic potash and concentrated aqueous potash at 230—250° attack it, the bromine being apparently displaced by hydroxyl.

By the action of a mixture of sulphuric and fuming nitric acids, preferably at 100°, it yields a mixture of two nitro-derivatives, which may be separated by taking advantage of the difference in their solubility in alcohol. The first compound remains as a green, pulverulent mass when the product of the reaction is extracted with alcohol, and it is also insoluble in ether, dilute and concentrated mineral acids, but it crystallises from chloroform in beautiful, six-sided tablets, or prisms, which melt at 215—216°. On reduction with alcoholic hydrochloric acid and stannous chloride, it yields the stannochloride of the corresponding amido-compound, $C_9NH_3Br_3{\cdot}NH_2,HSnCl_3$, crystallising in red prisms or needles, which on successive treatment with hydrogen sulphide and soda, yield the free base. The latter may be extracted with ether, and the residue remaining on evaporation washed with a little water, and crystallised from alcohol. Thus obtained, it forms yellow, plastic needles melting at 196°, scarcely soluble in hot water, readily in alcohol, ether, and chloroform. Its *hydrochloride* is very unstable, and forms blood-red prisms, and the *platinochloride* forms yellow or red, four-sided tablets or prisms which are decomposed by water.

The second nitro-1 : 4 : 4′-tribromoquinoline is obtained from the alcoholic extract, and crystallises in small, white, silky needles which quickly become yellow or green. It melts at 195°.

The residue in the retort, after distilling the product of the reaction of bromine on 1-bromoquinoline in a current of steam, yields on solution in hydrochloric acid, and fractional precipitation with water, a *tetrabromoquinoline*, $C_9NH_3Br_4$, which crystallises in slender, white needles melting at 197—198°. It does not appear to form salts.

In the more volatile portions of the steam distillate 4 : 4′-dibromoquinoline was also identified. H. G. C.

Conversion of the Homologues of Indole into Quinoline-derivatives. By G. MAGNANINI (*Gazzetta*, 19, 569—577).—*Methylquinoline.*—When methylketole is heated in a sealed tube with concentrated hydrochloric acid for 6 to 7 hours at 220—230°, and the product is freed from hydrochloric acid, steam distilled, made alkaline, and redistilled, a mixture of aniline with another basic compound passes over. The new base, when pure, boils at 250°, and has a strong odour of quinoline. It is a tertiary base, and does not yield a nitroso-derivative with potassium nitrite and sulphuric acid. The *platinochloride*, $(C_{10}NH_9)_2,H_2PtCl_6$, and the *aurochloride*, $C_{10}NH_9,HAuCl_4$, are well crystallised salts.

Chloroquinaldine, $C_{10}NH_8Cl$, is prepared by gradually adding chloroform to a mixture of methylketole and sodium ethoxide. The action is very violent, the product being partially resinified, but heat must be applied to complete the reaction. The pure base, obtained by decomposing the picrate, crystallises from dilute boiling alcohol in very slender, thin, white needles, melts at 71—72°, and smells strongly of quinoline. It shows feeble basic properties; the *platinochloride* crystallises in orange needles; the *picrate* is a sparingly soluble salt, which crystallises in yellow needles, and melts at about 223° with decomposition.

Bromoquinaldine is prepared in a manner analogous to the chlorinated derivative, and has very similar properties; it crystallises from alcohol in white needles, and melts at 78°; the *picrate* crystallises in monoclinic, colourless needles, $a : b : c = 0·90992 : 1 : 0·62391$, $\beta = 64° 31′ 33″$; faces observed (110), (001), $(\bar{1}11)$. It melts into a black liquid at 224—225°. When bromoquinaldine is heated with hydriodic acid and amorphous phosphorus for 5—6 hours at 180°, it loses bromine, and a base is left which smells strongly of quinaldine, and forms a *picrate* melting at 191° and a methiodide melting at 195°; the latter gives a carmine coloration with a concentrated solution of potash, exactly like the quinaldine methiodide obtained by Doebner and Miller (Abstr., 1884, 183). The base is probably quinaldine, but no analysis was made, on account of want of material.

Chlorolepidine, $C_{10}NH_8Cl$, isomeric with chloroquinaldine and with Knorr's chlorolepidine (Abstr., 1887, 159), is obtained by the action of chloroform on scatole; it crystallises from dilute boiling alcohol in silky needles melting at 54—55·2°; the *picrate* is a very sparingly soluble, yellow compound, melting at 208—208·5°; the *aurochloride* melts at 163·5—164·5°.

Bromolepidine, obtained by the action of bromoform on scatole, melts at 58·5—59·5°, and its properties are analogous to those of the previous bases; the *picrate* melts with decomposition at 214—215°. The author considers his chloroquinaldine and chlorolepidine to be 3′ : 2′- and 3′ : 4′-chloromethylquinolines respectively.

The Halogen Alkyloxides of Orthohydroxyquinoline and Parahydroxyquinoline. By A. Claus and H. Howitz (*J. pr. Chem.* [2], 42, 222—232).—Lippmann and Fleissner, in their investigation of the action of methyl iodide on orthohydroxyquinoline, came to the conclusion that the reaction does not proceed in the normal manner, but that a molecular compound of methoxyquinoline hydriodide and hydroxyquinoline methiodide, $C_9NH_6(OMe),HI + C_9NH_6(OH),MeI$, is formed, as on treatment with alkali they found that only half of the iodine was readily removed, a compound being formed to which they gave the formula $C_{19}H_{20}N_2O_2I$. The authors have repeated these experiments, and find the additive compound is readily obtained by heating orthohydroxyquinoline and methyl iodide in a sealed tube at 100° without any solvent. It crystallises from water in lustrous, yellow tablets of the composition $C_9NH_6(OH)MeI + H_2O$, and has all the properties mentioned by Lippmann and Fleissner. The corresponding chloride was also prepared from the iodide by treatment with silver chloride, and its molecular weight ascertained by Raoult's method. This agreed with the simple formula given above, and not with the double formula of Lippmann and Fleissner. It would, therefore, appear that, on treatment with alkalis, 2 mols. of the methiodide must take part in the reaction in the following manner:—

$$HO{\cdot}C_9NH_6MeI + HO{\cdot}C_9NH_6MeI = HO{\cdot}C_9NH_6Me{\cdot}O{\cdot}C_9NH_6MeI.$$

In confirmation of this supposition the authors find that hydriodic acid reconverts this iodide into the original methiodide, and that with hydrochloric acid it yields a mixture of the methiodide and methyl chloride in molecular proportion, whereas, if Lippmann and Fleissner's supposition were correct, the hydrochloride of the compound $C_{19}H_{20}N_2O_2I$ should have been formed.

Lippmann and Fleissner also state that methyl iodide converts this iodide into a new compound of the formula $C_{21}H_{22}N_2O_2I_2 + 2H_2O$, whereas, according to the authors' views, this should consist of a mixture of hydroxyquinoline methiodide and methoxyquinoline methiodide. The fractional crystallisation of the product from water has shown that such is really the case, the above-mentioned compounds having both been isolated and compared with the compounds obtained directly by the usual reactions. Orthomethoxyquinoline methiodide, $MeO{\cdot}C_9NH_6MeI + H_2O$, crystallises in pale-yellow, lustrous prisms, which lose their water of crystallisation at 100°, become red at 120°, and melt, with complete decomposition, at 160°. It does not lose hydrogen iodide on treatment with potash in the cold.

Parahydroxyquinoline also combines with methyl iodide, forming a *methiodide*, $HO{\cdot}C_9NH_6MeI,H_2O$, which crystallises from water in reddish-yellow prisms. These lose their water of crystallisation at 100°, and commence to decompose at 225—230°. From alcohol it crystallises in greenish-yellow, anhydrous plates. The corresponding *parahydroxyquinoline methochloride*, $HO{\cdot}C_9NH_6MeCl$, is obtained by treating the iodide with silver chloride, and crystallises from water in large, yellowish prisms, which also contain 1 mol. H_2O. Unlike the ortho-compounds, these substances readily lose all the halogen on treatment even with ammonia, the compounds formed being at present under examination. H. G. C.

Acid Derivatives of Orthamidoquinoline. By G. M. Kyritz (*Arch. Pharm.*, 228, 362—373).—Satisfactory results in the preparation of an orthonitroquinoline and its derived amido-quinolines can be obtained with commercial quinoline (coal-tar quinoline) when it is freed from its homologues by fractional distillation and conversion into the zinc double salt. The quinoline is then nitrated and freed from para- and meta-nitroquinoline by partial fractional precipitation and recrystallisation from alcohol. The nitroquinoline is reduced with stannous chloride and hydrochloric acid, the resulting base set free by the addition of sodium hydroxide, and distilled over with steam from a metallic retort, when a greater yield is obtained than if a glass retort is employed. The base is precipitated from the distillate with picric acid, and the picrate is decomposed by means of potassium hydroxide, taken up in ether, neutralised with sulphuric acid, freed from ether by evaporation, again set free by sodium hydroxide, and distilled off. Scaly, white plates of orthamidoquinoline, $C_9NH_6{\cdot}NH_2$ are thus obtained, which melt at 67°. *Acetorthamidoquinoline*, $C_9NH_6{\cdot}NHAc$, is produced by heating the amido-compound with acetic anhydride for 20 hours on the oil-bath. The brown mass poured into hot water, heated with animal charcoal, and filtered, gives long, white crystals which melt at 102·5°. Acetic chloride, and also glacial acetic acid, yields the same result. The compound has a bitter taste, is very soluble in 95 per cent. alcohol, also in ether, benzene, and chloroform. In cold water it is sparingly soluble; in hot water it is relatively easily soluble. At a temperature above 300°, it distils without decomposition.

Phthalylorthamidoquinoline, $C_9NH_6{\cdot}N{:}(CO)_2{:}C_6H_4$, is produced by the action of phthalic anhydride on the amido-base. At 85° to 88° the mixture suddenly froths up; it is then heated at 130° for 1½ hours, the excess of phthalic anhydride is removed by means of benzene, the dried residue dissolved in hot alcohol, decolorised by animal charcoal, and set to crystallise. The phthalyl compound forms small, white crystals, which melt at 227·5°. It is almost insoluble in cold and hot water. Alcohol dissolves it on long boiling; hot chloroform and ether dissolve it somewhat easily; in cold ether it is almost insoluble. Warmed with sulphuric acid, it is decomposed into its constituents. Its boiling point is above 200°. J. T.

Regularities in the Oxidation of Quinoline-derivatives. By W. v. Miller (*Ber.*, 23, 2252—2273).—The behaviour of various alkyl-derivatives of quinoline, on oxidation with chromic acid in warm dilute sulphuric acid, has been examined, and is described below; from the results obtained by the author and many others the following general conclusions may be drawn:—

All methyl- and ethyl-quinoline-derivatives in which the alkyl radicle is situated in the pyridine nucleus are oxidised by chromic acid to the corresponding quinolinecarboxylic acid; longer side chains are also converted into the carboxyl-group.

When there are two methyl-groups in the pyridine-ring, the radicle in the 4'-position is most readily, that in the α-position less readily, oxidised; 3' : 4'-dimethylquinoline, for example, is converted into 3'-methylcinchoninic acid.

A methyl-group in the pyridine ring is less readily oxidised than one situated in the benzene nucleus; this is also true, even when the side chain in the pyridine ring is the longer of the two, provided it is in the 2'-position.

Of two alkyl radicles, both of which are in the pyridine ring, the one of higher molecular weight is the more readily oxidised.

When two methyl-groups are present in the pyridine, and one in the benzene nucleus, the latter is oxidised first; 2'-ethyl-3'-methyl-3-toluquinoline forms an exception to this rule (see below).

A methyl-group in the ortho-position in the benzene nucleus is not so readily oxidised as the same radicle in the para-position.

It seems, therefore, that as regards methyl-groups, the order of stability is as follows:—α-, β-, γ-, ortho-, meta-, and para- (=2', 3', 4', 1, 2, 3), the radicle in combination with the nitrogen-atom being the most readily oxidised. When a carboxyl-group is present in one nucleus, a saturated side chain in the other ring is only oxidised with difficulty.

3'-*Methylcinchoninic acid*, $C_{11}H_9NO_2$, is formed when 3' : 4'-dimethylquinoline is oxidised with chromic acid. It crystallises from water in colourless, microscopic plates, melts at 254°, and is readily soluble in hot water, but only moderately easily in alcohol, and insoluble in ether, benzene, and light petroleum; on distillation with soda-lime, it yields 3'-methylquinoline.

Orthotoluquinaldine hydrochloride crystallises in colourless needles, the *picrate*, $C_{11}H_{11}N,C_6H_3N_3O_7$, in golden plates, and the *nitrite*, $C_{11}H_{11}N,HNO_2$, in needles; when the base is oxidised with chromic acid, it is converted into quinaldineorthocarboxylic acid (m. p. 151°).

Benzylidenequinoline 3-carboxylic acid, $C_{19}H_{13}NO_2$, prepared by heating quinaldineparacarboxylic acid with benzaldehyde at 130—150°, in presence of zinc chloride, crystallises from hot dilute acetic acid in yellow needles, melts at 264°, and is insoluble in most ordinary solvents except hot dilute alcohol, acetic acid, and alkalis; on oxidation with chromic acid, it yields a yellow, crystalline acid, $C_{11}H_7NO_4$, which turns brown at 265°, and melts at 275—280° with decomposition.

Quinaldine-3 : 4'-dicarboxylic acid, $C_{12}H_9NO_4$, was obtained as a colourless powder by heating acetaldehyde with paramidobenzoic acid and pyruvic acid in alcoholic solution. It softened at about 260°, but had no definite melting point; when heated it yields quinaldine The copper salt, $C_{12}H_7NO_4Cu$, is crystalline.

Ethylquinoline-3 : 4'-dicarboxylic acid, $C_{13}H_{11}NO_4$, prepared in like manner from propaldehyde, is a colourless, amorphous powder.

When metatoluquinaldine is oxidised with chromic acid, it is converted into quinaldine-2-carboxylic acid (m. p. 284°); paratoluquinaldine, under the same conditions, yields quinaldine-3-carboxylic acid (m. p. 256°), the *platinochloride* of which has the composition $(C_{11}H_9NO_2)_2,H_2PtCl_6 + 4H_2O$.

4'-*Methyl-3-toluquinoline*, formed by the condensation of paratoluidine with acetone and paraformaldehyde, is an agreeably smelling oil, boiling at 273—274°; the *platinochloride*, $(C_{11}H_{11}N)_2,H_2PtCl_6 + 2H_2O$, crystallises from concentrated hydrochloric acid in needles, and melts at 238°. When the base is oxidised with chromic acid, it is converted into a methylquinolinecarboxylic acid, $C_{11}H_9NO_2$, and a very small quantity of another acid, which was not analysed. The former crystallises from hot water in needles, melts at 250—270° with decomposition, and yields lepidine on distillation with soda-lime.

3-*Methyl*-2′-*ethylcinchoninic acid*, $C_{13}H_{13}NO_2$, obtained by the condensation of paratoluidine with propaldehyde and pyruvic acid, crystallises from hot alcohol in microscopic plates, sinters together at 242°, and melts at 244—248° with decomposition; it is sparingly soluble in cold water and alcohol, but readily in hot alcohol. The *barium* salt, $(C_{13}H_{12}NO_2)_2Ba$, crystallises from water in yellow plates; the *silver* salt, $C_{13}H_{12}NO_2Ag$, is gelatinous. The *hydrochloride* crystallises in long needles. When the acid is distilled, it yields 2′-ethyl-3-toluquinoline, identical with the base obtained by Harz (Abstr., 1886, 261). The compound of the composition $C_{13}H_{13}NO$ (*loc. cit.*) is the aldehyde of 3-methyl-2′-ethylquinoline-3′-carboxylic acid.

When 2′-ethyl-3-toluquinoline is oxidised with chromic acid, it is converted into a resinous acid melting at about 235°, which, on distillation with soda-lime, yields 2′-ethylquinoline.

2′-*Ethyl*-3′-*methylquinoline*-1-*carboxylic acid*, $C_{13}H_{13}NO_3$, is formed by the oxidation of 2′-ethyl-1 : 3′-dimethylquinoline. It separates from hot alcohol in crystals, melts at 215—216°, and is only sparingly soluble in hot water, but more readily in hot alcohol. The *barium* salt, $(C_{13}H_{12}NO_2)_2Ba + \frac{1}{2}H_2O$, crystallises in plates, and is moderately easily soluble in water. When the acid is distilled over soda-lime, it yields 2′-ethyl-3′-methylquinoline (m. p. 55—56°).

3 : 2′ : 3′-*Trimethylquinoline*, $C_{12}H_{13}N$, the condensation-product of tiglic aldehyde and paratoluidine, separates from light petroleum in large, nodular crystals, melts at 86—87°, and boils at 285°; it is readily soluble in ether, but only sparingly in benzene and light petroleum, and insoluble in water. The *platinochloride*,

$$(C_{12}H_{13}N)_2,H_2PtCl_6 + 2H_2O,$$

crystallises in brown plates, the *chromate* in orange-red plates, and the *picrate* in yellow plates, melting at 212° with decomposition. The *hydrochloride* and the *sulphate* are very readily soluble in water, but the *nitrate* is more sparingly soluble. On oxidation, the acid is converted into 2′ : 3′-dimethylquinoline-3-carboxylic acid, $C_{12}H_{11}NO_2$; this compound crystallises in needles, sinters together at 258°, melts at 270° with decomposition, and yields 2′ : 3′-dimethylquinoline (m. p. 67—68°) on distillation with soda-lime.

1 : 3 : 3′-*Trimethyl*-2′-*ethylquinoline*, $C_{14}H_{17}N$, can be obtained by the condensation of asymmetric metaxylidine with propaldehyde. It crystallises from hot alcohol in plates, melts at 62°, boils at 291°, and is volatile with steam; it is readily soluble in ether, benzene, and light petroleum, but more sparingly in alcohol. The *picrate*, $C_{14}H_{17}N,C_6H_3N_3O_7$, crystallises from hot alcohol in yellow

needles; the *platinochloride*, $(C_{14}H_{17}N)_2,H_2PtCl_6$, *nitrate*, *sulphate*, and *dichromate* are crystalline. The *hydrochloride*, $C_{14}H_{17}N,HCl + 3H_2O$, crystallises in colourless needles. The *methiodide*, $C_{14}H_{17}N,MeI$, crystallises in yellowish needles, and is soluble in hot water and alcohol. The *nitro*-derivative, $C_{14}H_{16}N\cdot NO_2$, crystallises from alcohol in needles, melts at 90°, and is readily soluble in ether, benzene, and light petroleum, but only sparingly in water. The *dinitro*-compound, $C_{14}H_{15}N(NO_2)_2$, crystallises from hot alcohol in colourless plates, and melts at 152·5°. The *sulphonic acid*, $C_{14}H_{16}N\cdot SO_3H$, crystallises in small, colourless needles, and is sparingly soluble in water.

Ethyltrimethyltetrahydroquinoline, $C_{14}H_{21}N$, prepared by reducing the base just described, is an oil boiling at 287—289°; it forms an *acetyl*- and a *nitroso*-derivative. The *picrate*, $C_{14}H_{21}N,C_6H_3N_3O_7$, melts at 146°.

3 : *3'-Dimethyl-2'-ethylquinoline*-1-*carboxylic acid*, $C_{14}H_{15}NO_2$, is formed when the ethyltrimethyl base is oxidised with chromic acid; it separates from alcohol in colourless crystals, melts at 182—183°, and is readily soluble in alcohol and water, but sparingly in benzene and chloroform, and insoluble in ether; on distillation with soda-lime, it is converted into 3 : 3'-dimethyl-2'-ethylquinoline (compare Harz, *loc. cit.*). F. S. K.

Action of Phenylhydrazine on Pyrocinchonic, α-Dichloro-symmetrical-dimethylsuccinic, and α-Dichloropropionic Anhydrides, and on Pyrocinchonic Chloride. By R. Otto and G. Holst (*J. pr. Chem.* [2], 42, 65—81; compare Abstr., 1887, 669).—When solutions of pyrocinchonic anhydride (1 mol.) and phenylhydrazine (2 mols.) in a little benzene are mixed, *phenylhydrazine pyrocinchonylphenylhydrazinate*,  $\begin{array}{l}\mathrm{MeC\cdot CO\cdot NH\cdot NHPh}\\ \;\|\\ \mathrm{MeC\cdot COO\cdot NH_3\cdot NHPh}\end{array}$, is produced as a bulky precipitate, which dries to a white, crystalline powder, but cannot be recrystallised (see below); dilute hydrochloric acid decomposes it into phenylhydrazine hydrochloride and pyrocinchonic anhydride. When it is heated at 110—120°, it decomposes into water, phenylhydrazine, and a substance which melts at 129°; the latter, *β-pyrocinchonylphenylhydrazine*, is most easily obtained by dissolving the phenylhydrazinate in hot dilute alcohol; on cooling the solution, the new substance crystallises out.

β-Pyrocinchonylphenylhydrazine,  $\begin{array}{l}\mathrm{MeC\cdot CO\cdot NH}\\ \;\|\qquad\quad\;\,|\\ \mathrm{MeC\cdot CO\cdot NPh}\end{array}$, forms beautiful, yellow, monosymmetrical prisms (crystallography given), which melt at 129°, and are insoluble in water, but soluble in most other solvents. Its constitution is settled by the close analogy which its preparation bears to that of Hotte's β-phthalylphenylhydrazine (Abstr., 1887, 669). Hotte, however, did not obtain a *phenylhydrazine β-phthalylphenylhydrazinate*, so to complete the chain of evidence the author has prepared this substance; it separates from a hot alcoholic solution as a white, prismatic, crystalline powder.

α-Pyrocinchonylphenylhydrazine,  $\begin{array}{l}\mathrm{MeC\cdot CO}\\ \;\|\\ \mathrm{MeC\cdot CO}\end{array}\!\!>\mathrm{N\cdot NHPh}$, is prepared by mixing cooled ethereal solutions of pyrocinchonic chloride (1 mol.), prepared by the action of phosphoric chloride on pyrocinchonic anhydride and phenylhydrazine (3 mols.; compare Pickel, Abstr., 1886, 545). The precipitate thus obtained is washed with warm water and crystallised from dilute alcohol; it forms soft, yellow needles, melts at 187°, and is soluble in hot alcohol and benzene.

When phenylhydrazine (4 mols.) acts on α-dichloro-symmetrical-dimethylsuccinic anhydride (1 mol.), phenylhydrazine hydrochloride, nitrogen, benzene, and β-pyrocinchonylphenylhydrazine are formed. This reaction is remarkable, because Otto and Beckurts (Abstr., 1885, 753) could only obtain very little pyrocinchonic acid by the action of "molecular" silver on dichlorodimethylsuccinic acid

α-Dichloropropionic anhydride, obtained by acting on the acid with phosphorus trichloride, is a colourless liquid boiling about 200°, of peculiar odour, and exciting a copious flow of tears.

A *propionylphenylhydrazine*, $CMe(N_2HPh)\cdot CO\cdot NH\cdot NHPh$, is formed when phenylhydrazine (8 mols.) acts on α-dichloropropionic anhydride (1 mol.), a phenylhydrazine residue taking the place of both chlorine-atoms; it crystallises in nearly white, lustrous plates melting at 163°, and is soluble in hot water, alcohol, ether, and benzene.

A. G. B.

Coniceïnes. By E. Lellmann (*Ber.*, 23, 2141—2142).—All the three methods described by Hofmann (Abstr., 1885, 401) for the preparation of α-coniceïne yield different products. The base obtained by treating conhydrine with hydrochloric acid is probably α-coniceïne; the compound formed by the action of hydriodic acid on conhydrine the author names ε-coniceïne, and that obtained by treating bromoconiine with sulphuric acid, δ-coniceïne.

α-Coniceïne boils at 158°, is very hygroscopic, has a sp. gr. of 0·893, and forms a deliquescent hydrochloride; its picrate melts at 224° and its aurochloride at 196—198° with previous decomposition.

δ-Coniceïne boils at 158°, is not hygroscopic, and has a sp. gr. of 0·8976; it is lævo-rotatory (−7° 48'), and its *hydrochloride* is stable in the air. The *picrate* melts at 226°, and the *aurochloride* at 207° with slight decomposition; the *platinochloride* is moderately easily soluble.

ε-Coniceïne boils at 150—151° and is not hygroscopic; it is dextrorotatory (42°), and its *hydrochloride* is very deliquescent. The *picrate* melts at 223—224°, and the *aurochloride* at 175°, seemingly without decomposition; the platinochloride is very readily soluble.

F. S. K.

Strychnine. By H. Beckurts (*Arch. Pharm.*, 228, 313—325).—The strychnine employed, prepared from commercial nitrate, crystallised in anhydrous, four-sided prisms, which melted with blackening at 265°. If the temperature be raised quickly, the melting point appears to be considerably higher. Several analyses were made, the results agreeing best with the formula $C_{21}H_{22}N_2O_2$. Laurent (*Annalen*, 69, 14) has shown that the action of bromine on an aqueous solution of strychnine hydrochloride converts it into bromostrychnine, which is precipitable by ammonia as a white, crystalline compound.

α-Monobromostrychnine, $C_{21}H_{21}BrN_2O_3$, is obtained by adding bromine (2 atoms) in the form of bromine-water to a solution of strychnine hydrobromide (1 mol.), and then precipitating with ammonia. By slow evaporation of the alcoholic solution of this precipitate, well-formed, rhombic plates are obtained which melt at 222°, and are only very slightly soluble in water, slightly soluble in ether, and easily in chloroform, benzene, and alcohol. The aqueous solution has an alkaline reaction and a very bitter, persistent taste. Its colourless solution in concentrated sulphuric acid gives a momentary, light-blue coloration on the addition of potassium dichromate. The aqueous solution gives precipitates with tannin, potassium mercury iodide, phosphotungstic acid, phosphomolybdic acid, potassium chromate, and platinum chloride. Monobromostrychnine hydrochloride, $C_{21}H_{21}BrN_2O_2,HCl$, and the corresponding hydrobromide, nitrate, and sulphate, the latter with 7 mols. H_2O, are easily obtained in crystalline forms

α-Monobromostrychnine methiodide, $C_{21}H_{21}BrN_2O_3,MeI$, is obtained by warming an alcoholic solution of *α*-monobromostrychnine with excess of methyl iodide for several hours on the water-bath. The white, pearly, crystalline laminæ are sparingly soluble in alcohol, ether, chloroform, and water; on heating, they are charred without melting. The action of light turns them yellow, and they do not give the strychnine reaction with sulphuric acid and potassium dichromate. The corresponding *hydroxide*, $C_{21}H_{21}BrN_2O_3,MeOH + 4H_2O$, is obtained in slender, white needles on digesting the methiodide compound with excess of silver oxide for a short time on the water-bath, and filtering off the silver iodide formed; it chars at 260° without melting, is readily soluble in water and dilute alcohol, becomes yellow on exposure to light, and gives a very changeable, violet coloration with sulphuric acid and potassium dichromate.

Mononitrobromostrychnine, $C_{21}H_{20}(NO_2)BrN_2O_3$, is prepared by gradually adding 5 grams of monobromostrychnine nitrate dried at 105° to 50 grams of concentrated sulphuric acid cooled by a freezing mixture. After three days, the dark-yellow liquid is poured into 5 litres of water, and, after cooling, supersaturated with ammonia. The yellow, flocculent precipitate, recrystallised from alcohol, gives pale-yellow prisms, which on heating intumesce and coke, dissolve easily in acetone and dilute alcohol, but with difficulty in chloroform, benzene, and water. With sulphuric acid and potassium dichromate, the compound gives the strychnine reaction. The base does not give well-crystallised salts with acids. The hydrobromide and hydrochloride are yellow and amorphous. With platinic chloride, the base dissolved in hydrochloric acid gives a yellow, crystalline precipitate of the platinochloride, $[C_{21}H_{20}Br(NO_2)N_2O]_2,H_2PtCl_6$, which is sparingly soluble in alcohol.

Amidobromostrychnine, $C_{21}H_{20}Br(NH_2)N_2O_2$, is produced by heating a hydrochloric solution of the corresponding nitro-derivative for some hours with tin-foil on the water-bath; the dissolved tin is removed by hydrogen sulphide and the amido-compound precipitated by ammonia. On recrystallising from alcohol of sp. gr. 0·93, small, brownish needles are obtained. The compound is only slightly soluble in chloroform, acetone, and ether; the solutions quickly decompose. It softens at 140° and melts at 180° to a brown liquid. The solutions in acidified water also quickly decompose. The yellow platinochloride soon becomes violet on exposure to air. J. T.

Brucine. By H. BECKURTS (*Arch. Pharm.*, **228**, 326—330).—Laurent has described a monobromobrucine, but the author did not succeed in obtaining it by the method given. If bromine-water is added to an aqueous solution of brucine hydrobromide in the proportion of 2 atoms of bromine to 1 molecule of the salt, a precipitate appears which is first violet, then brown, and finally pure yellow; it has the formula $C_{23}H_{26}N_2O_4Br_3$. This compound dissolved in dilute alcohol, has an alkaline reaction; in the air it gradually forms an intense, red syrup. At 150° it evolves bromine, becoming brown, and at higher temperatures it chars. The aqueous solution of the compound has an acid reaction, and on concentration white or brownish plates of brucine hydrobromide, $C_{23}H_{26}N_2O_4,HBr + 3H_2O$, crystallise out. The mother liquor on evaporation gives a residue which appears to be dibromobrucine, $C_{23}H_{24}Br_2N_2O_4$. 10 grams of brucine treated with 200 grams of chlorine-water dissolved, but gave no crystalline product on evaporation; the deep-red, amorphous, dry residue, *dichlorobrucine*, $C_{23}H_{24}Cl_2N_2O_4$, is insoluble in ether, chloroform, benzene, and absolute alcohol. If a mixture of brucine and strychnine is treated with chlorine-water, the former goes into solution as dichlorobrucine, and the residue of strychnine salt will then give the strychnine reaction with sulphuric acid and potassium dichromate. J. T.

Stereochemistry of Nitrogen. By C. A. BISCHOFF (*Ber.*, **23**, 1967—1972).—It is generally assumed that in the case of a compound containing three radicles combined with a trivalent nitrogen-atom, no isomerides can exist. The author believes, however, that it is possible such isomerides may be found where the radicals combined with the nitrogen-atom become more complex, in which case, judging from his experience in the succinic acid group, the various isomerides would not so readily pass one into the other. He further points out that an isomeric methyldiphenylamine has already been described by Girard, Vogt, and Bardy, which Beilstein (*Handbuch*, **2**, 255), on account of the theoretical impossibility of an isomeric methyldiphenylamine, regards as phenyltoluidine. The physical constants of the compound do not agree well with this supposition, and a further investigation of the matter is therefore necessary.

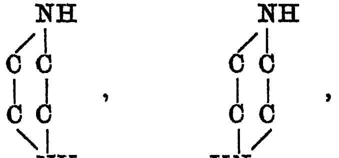
A second group of nitrogen compounds in which isomerides may possibly exist, contains those in which the nitrogen-atom is combined with carbon by double or triple linkage. In this case, as already frequently stated, the isomerism is due to the fact that the mutual approximation of the doubly-linked atoms hinders the freedom of rotation. The third group, quite distinct from both the foregoing, is that of the hydroxylamine-derivatives.

According to the author's ideas, the nitrogen-atom may be graphically represented in a similar manner to the carbon-tetrahedron by a quadratic pyramid; in its compounds, as, for instance, ammonium chloride, the four hydrogen-atoms are situated at the four corners of the base, and the chlorine-atom at the apex. The direction of the valency at the apex makes, with that of each of the valencies at the base, an angle of 120°. In hydroxylamine, one atom of hydrogen is regarded as situated at the apex, and the remaining atoms of hydrogen and the oxygen-atom at the base. Isomerides can then be formed by the substitution of the hydrogen at the apex or one of those at the base by monovalent radicles. When, as in the case of the oximes, two hydrogen-atoms are replaced, three isomerides are possible, in which either both the hydrogen-atoms at the base are replaced, or the hydrogen-atom at the apex and one of those at the base. If the pentavalent nitrogen-atom passes into a trivalent atom, as when ammonium chloride loses hydrogen chloride, the three hydrogen-atoms rearrange themselves symmetrically, the directions of the three remaining valencies then forming with one another an angle of 120°.

H. G. C.

Stereochemical Studies in the Piperazine-group. By C. A. Bischoff (*Ber.*, **23**, 1972—1976).—The object of the researches of the author and his pupils on the mixed carbon and nitrogen rings is eventually to ascertain under what conditions the formation of closed chains of the general formula $A{\cdot}N{<}{}^{Cx}_{Cy}{>}N{\cdot}B$ takes place, A and B representing monovalent radicles, and x and y the number of carbon-atoms between the two nitrogen-atoms. In the present paper, only the case where $x = y = 2$ is discussed, that is, the formation of the members of the piperazine-group.

Starting with the assumption that the valencies of the carbon-atom make with one another an angle of 109° 28′, and those of the trivalent nitrogen-atom 120°, it is found that two spacial configurations of the piperazine skeleton are possible, namely:—



I. II.

the conditions of equilibrium being more favourable in the second case. The results given in some of the following abstracts appear to show that isomerides corresponding with these formulæ do exist. Moreover, it is found that the nature of the radicals A and B exerts an influence on the relative facility with which one form passes into the other, and also appears to determine whether ring-formation takes place or not. Thus, whilst ethylene-derivatives readily condense with all primary amido-bases to form piperazines, the propylene-derivatives do not behave in a similar manner, and orthotoluidine does not form a closed chain under circumstances in which paratoluidine and aniline readily do so.

The influence of the alkyl-groups may also be observed in the closed chains containing an oxygen-atom in the ring, especially as regards the ease with which they are attacked by potash.

The action of nitrous acid on the piperazines does not always take place in the same manner, compounds being formed which in some cases give Liebermann's reaction, and in others not, whilst in certain cases the action is chiefly an oxidising one. An important difference between the piperazine- and piperidine-derivatives is that, in the former, hydrogen is never removed by oxidation without oxygen being substituted for it.

H. G. C.

Diphenylpiperazine. By C. A. Bischoff and C. Trapfsonzjanz (*Ber.*, 23, 1977—1981).—The preparation of diphenylpiperazine has already been described (Abstr., 1889, 1010). Nitrous acid acts on diparamethoxydiphenylpiperazine,

$$MeO\cdot C_6H_4\cdot N{<}\begin{matrix}CH_2\cdot CH_2\\ CH_2\cdot CH_2\end{matrix}{>}N\cdot C_6H_4\cdot OMe,$$

(*loc. cit.*) with formation of three compounds, the first of which crystallises in reddish-yellow needles melting at 150—155°, the second, in brownish-black needles melting at 155°, and the third, in red plates melting at 215—220°. The first two give Liebermann's reaction, but not the third.

When phenetidine hydrochloride (34 grams) is treated with ethylene bromide (18 grams), sodium carbonate (34 grams), and water (200 grams), besides diparaethoxydiphenylpiperazine, the secondary base, *ethylene diparaethoxydiphenyldiamine*,

$$C_2H_4(NH\cdot C_6H_4\cdot OEt)_2,$$

is obtained. It crystallises from a mixture of ether and alcohol in colourless plates melting at 98°, and on further treatment with ethylene bromide yields the above diparaethoxydiphenylpiperazine. This melts at 218—223°, and by the action of nitrous acid yields *mononitrosodiparaethoxydiphenylpiperazine*, $C_{20}H_{25}N_3O_3$, melting at 80°, and decomposing at 170°, and a compound, $C_{20}H_{24}N_4O_6$, which forms yellowish-red needles melting at 120—130°.

An attempt was made to obtain a piperazine from propylene bromide by the action of aniline and sodium carbonate, but without success.

H. G. C.

Diphenyl-αγ- and αδ-diketopiperazines. By C. A. Bischoff and A. Hausdörfer (*Ber.*, 23, 1987—1991).—The phenylglycin required for the preparation of diphenyl-αγ-diketopiperazine was obtained by Hausdörfer's method (Abstr., 1889, 1013), which gives a better yield than that proposed by Rebuffat (*Gazzetta*, 20, 122).

Diphenyl-αγ-diketopiperazine, $PhN{<}\begin{matrix}CH_2\cdot CO\\ CO\cdot CH_2\end{matrix}{>}NPh$, is only acted on by the gaseous mixture of oxides of nitrogen evolved from arsenious oxide and nitric acid, the quantity of substance obtained being then only small and difficult to purify. By the oxidation of this piperazine, the authors obtained results agreeing exactly with those of Abenius (this vol., p. 525).

The compound obtained as a bye-product on heating ethoxyphenylglycin (Abstr., 1889, 1012) when heated with acetic anhydride gives a *diparaethoxyphenyldiketopiperazine*, which is not identical with the αγ-compound previously obtained, and is probably the αδ-compound, $EtO\cdot C_6H_4\cdot N<\begin{matrix}CH_2\cdot CO\\ CH_2\cdot CO\end{matrix}>N\cdot C_6H_4\cdot OEt$. It forms colourless, lustrous tablets melting at 177—178°.

Diphenyl-αδ-diketopiperazine, $PhN<\begin{matrix}CH_2\cdot CO\\ CH_2\cdot CO\end{matrix}>NPh$, is acted on by nitrous acid with formation of a golden-yellow compound melting at 93°. It has the formula $C_{16}H_{14}N_2O_2$ or $C_{16}H_{12}N_2O_2$, and contains therefore no more nitrogen and oxygen than the original piperazine. It is at present undergoing further investigation. H. G. C.

Ortho- and Para-ditolylpiperazines and β-Dinaphthylpiperazine. By C. A. Bischoff and A. Hausdörfer (*Ber.*, 23, 1981—1986).—*Orthoditolylpiperazine*, $C_6H_4Me\cdot N<\begin{matrix}CH_2\cdot CH_2\\ CH_2\cdot CH_2\end{matrix}>N\cdot C_6H_4Me$, is obtained in the same manner as diphenylpiperazine, the yield in this case being the worst of any in the piperazine-group, ethyleneditolylamine being obtained as a bye-product in the reaction. Orthoditolylpiperazine melts at 169—171°, and yields on treatment with nitrogen trioxide in sulphuric acid solution a compound, $C_{16}H_{20}N_4O_4$ or $C_{18}H_{18}N_4O_4$, melting at 282°, which does not show Liebermann's reaction.

Paraditolylpiperazine is much more readily prepared than the ortho-compound, and is best crystallised from chloroform. It melts at 187°, and is converted by nitrous acid into a compound crystallising in red prisms and melting at 175°, which gives Liebermann's reaction.

β-Dinaphthylpiperazine, $C_{10}H_7\cdot N<\begin{matrix}CH_2\cdot CH_2\\ CH_2\cdot CH_2\end{matrix}>N\cdot C_{10}H_7$, obtained from β-naphthylamine, sodium carbonate, and ethylene bromide, forms colourless crystals melting at 228°. As a bye-product, the compound *ethylenedi-β-naphthyldiamine*, $C_2H_4(NH\cdot C_{10}H_7)_2$, is obtained; this forms colourless, lustrous plates or needles which melt at 149—150°. H. G. C.

Hydrastine: a Correction. By M. Heim (*Ber.*, 23, 2469).—The compound (m. p. 166—169°) obtained by Freund and Rosenberg (compare this vol., p. 533) from methylhydrastine methiodide by the action of alkalis, has the formula $C_{20}H_{22}O_9$, not $C_{20}H_{20}O_8$ as given. F. Schmidt prepared, by the same method, a compound of the formula $C_{20}H_{14}O_7$; the difference is possibly caused by the manner of drying, the one being done at ordinary temperatures, the other at 100°. J. B. T.

Conversion of Tropidine into Tropine. By A. Ladenburg (*Ber.*, 23, 2225; compare this vol., p. 1167).—Further experiments have shown that the base obtained by treating tropidine with hydrobromic acid in the cold is identical with tropine. F. S. K.

Physiological Chemistry.

Influence of Muscular Work, Hunger, and Temperature on the Exhalation of Carbonic Anhydride. By V. GRANDIS (*Chem. Centr.*, 1890, i, 1069; from *Arch. Italien de Biologie*, **12**).—Experiments with dogs gave the following results:—

1. More carbonic anhydride is exhaled during muscular work than when the animal is at rest, whatever the conditions as regards food are.

2. When both fasting and tired, the animals exhaled less carbonic anhydride than under normal conditions, although for the first few hours after work the amount exhaled was greater.

3. The weight of the animal decreases much more rapidly after exercise than when fasting, six hours' exercise causing as great a loss of weight as when the animal fasted for four days.

4. If, after a seven days' fast, the animal is fed with double the usual amount of food, it regains its weight in three or four days, but this cannot be accomplished with animal food only. The breathing is less rapid during fasting, as also is the heart's action, especially in a warm atmosphere.

J. W. L.

Glycogen in the Liver and Muscles. By E. HERGENHAHN (*Zeit. Biol.*, **27**, 215—227).—The conclusions from seven series of experiments, which are given with full analytical details and charts of results, are the following:—

1. The liver glycogen dwindles in hens after six days' inanition to very small quantities (0·0 to 0·098 gram; compare Prausnitz, this vol., p. 810).

2. The muscle glycogen, on the other hand, after the same period, is still present in considerable amount, although varying between wide limits (0·053 to 1·58 grams).

3. At the end of the period of abstinence, the store of muscle glycogen in all the experiments preponderated.

4. On the administration of cane-sugar, the liver glycogen soon shows a great increase; the muscle glycogen shows no important rise until 12 hours after the feeding.

5. As is shown graphically by curves, about six hours after the administration of cane-sugar as food, the liver glycogen has increased so much that it equals in amount the muscle glycogen. Later on, its amount exceeds that in the muscles, the time when this occurs varying with the dose; for instance, with

10 grams of cane-sugar, in 15 hours.
20 " " 20 "
30 " " 26 " .

6. The maximum of the liver glycogen occurs earlier when the dose of sugar is small; for instance,

Quantity of cane-sugar given.	Maximum of liver-glycogen appeared in—	Average amount of the maximum.
10 grams	12 hours	1·625 grams
20 "	16 "	1·980 "
30 "	20 "	3·585 "

7. The maximum of the muscle glycogen is independent of the amount of sugar administered, and appears 12 to 24 hours after the food is given.

8. As a rule, the maximum of the liver glycogen is somewhat greater than that of the muscle glycogen, but both are proportional to the amount of cane-sugar given.

9. The difference of time in the occurrence of the two maxima is lessened by increasing the amount of cane-sugar given. It vanishes with a dose of 30 grams. W. D. H.

Formation of Glycogen in Muscle with an Artificial Circulation. By E. Külz (*Zeit. Biol.*, **27**, 237—246).—Previous observers have stated that a liver freshly removed from the body continues to form glycogen from dextrose dissolved in blood artificially pumped through the organ. In the present research, similar experiments were made with the muscles of the lower extremities of dogs. These were, after the death of the animal, kept at the body temperature, and after an experiment lasting five or six hours were still found excitable and contractile when tested with an electric stimulus. A measured quantity of blood was pumped through each limb in some experiments, but that passed through one limb had a known quantity of dextrose or cane-sugar dissolved in it; at the end of the experiment the amounts of glycogen in each limb were estimated and compared with one another; the amount of sugar left in the blood was also estimated. In other experiments, the control limb was not subjected to an artificial circulation, but the glycogen in it was estimated immediately after death. In a third series of experiments, the estimations were made not for the entire limbs, but for individual muscles of the limbs. The third series is regarded as unsatisfactory; the corresponding muscles of the two sides were practically equal in so far as their glycogen was concerned, or if any difference at all occurred, the control muscle contained the more glycogen. The muscles, however, did not respond to the electric current, and so may be regarded as dead. Death does not occur so soon when the whole limb is left intact, and the results of experiments conducted on this plan are, therefore, regarded as more trustworthy. Here it was found (except in two instances where the differences are so small as to come within the limits of experimental errors) that the limb through which the blood containing sugar had been pumped contained the greater amount of glycogen. This is regarded as evidence that the muscles have in themselves the power of producing glycogen from sugar, and are not merely dependent on the liver for their supply of glycogen. W. D. H.

Phloridzin Diabetes. By F. Moritz and W. Prausnitz (*Zeit. Biol.*, **27**, 81—118).—J. v. Mering (*Verhandl. d. V and VI Congress inn. Med.*, *Zeit. klin. Med.*, **14**, 405; **16**, 431) has discovered in phloridzin an agent by means of which diabetes can be artificially produced in animals. Phloridzin is a glucoside, which, by boiling with an acid, is decomposed, yielding a sugar phlorose, which is almost identical with dextrose, and phloretin, which, by the action of caustic alkali, is split into phloroglucinol and phloretic acid. The constitution of phloridzin is not known with certainty; phloretic acid, however, is the acid of an aromatic alcohol, and phloroglucinol is a trihydric aromatic alcohol or phenol. It is probable that phloridzin contains free aromatic hydroxyl-groups. It therefore was necessary in the course of the investigation to determine the amount of ethereal hydrogen sulphate in the urine in addition to the sugar. The results of these experiments and others bearing on the influence of the drug on metabolism and other points may be thus stated:—

The phloridzin used was pure; it yielded phloretin which crystallised in needles melting at 226—230°, thus differing from that originally described by Stas (*Annalen*, **30**, 200), which crystallised in plates melting at 180°. A simple reaction for phloridzin is the red colour produced on evaporating it with a few drops of a solution of vanillin in alcohol, and a little hydrochloric acid. Iron chloride gives a brown coloration with solution of phloridzin. Neither of these tests, however, can be used for its identification in fæces, as they are not characteristic. Phloridzin may be best detected and estimated by the yield of sugar produced after hydrolysis with sulphuric acid. The absorption of phloridzin in the alimentary canal appears to be rapid and complete. After feeding an animal on the drug in doses of 1 gram per kilo. of body weight, it is not recognisable in the fæces. For a space of two days on the average after the administration of the drug, the urine contains a substance which gives a brown coloration with ferric chloride. The urine also contains an increased quantity of ethereal hydrogen sulphates on the day of the dose, and the succeeding day; the increase is so marked that it is only explicable on the grounds that part of the phloridzin given is combined in the urine as a sulphate. The following table represents the result of an experiment on a dog, bearing out this statement:—

Date.	Sulphuric acid.			Remarks.
	As normal sulphate (*a*).	As ethereal sulphate (*b*).	*a* : *b*.	
24th Nov. .	0·69	0·14	1 : 0·2	Normal.
4th Dec. .	0·85	0·11	1 : 0·13	Normal.
6th Dec. .	0·21	0·41	1 : 2·0	6 gr. of phloridzin given.
7th Dec. .	0·66	0·22	1 : 0·34	

The excretion of phloridzin, and the accompanying glycosuria, appears to be completed within the second day after its administration. The total quantity of sugar in the urine is far greater than can be accounted for by the phlorose derived from the drug itself; it is a form of sugar which completely disappears under the influence of yeast, and is thus dextrose, doubtless mixed with phlorose.

Phloretin also causes glycosuria, but not so markedly as does phloridzin. Phloroglucinol and phloretic acid do not produce this result. Phloridzin diabetes is analogous to the most severe form of human diabetes; it occurs whatever the diet may be: meat, carbohydrate, or fat, or mixtures of these, or when no food is given at all. The excretion of sugar begins about three hours after the drug has been given, rises quickly to a maximum, and as rapidly falls; this corresponds to the rate of absorption and excretion of the drug. The percentage sugar contents of the urine varies greatly. A minimum of 6 per cent. and a maximum of 13·5 per cent. were observed. It varies with the amount of phloridzin given, and also with the amount of food taken. In this latter particular an increase of meat in the diet produces a more marked effect than an increase of the carbohydrates: this is, probably, dependent on the slower absorption of starch. If one calculates the maximal amount of sugar theoretically possible from the food, after allowing for the carbon discharged as urea, it is found that the quantity of sugar in the urine is much less, but in the case of meat diet is greater than in the case of starchy foods. The output of sugar during hunger and during a fatty diet is very great, relatively much greater than when carbohydrates and meat are taken. The destructive metabolism of proteids during an abundant meat diet is only slightly increased by phloridzin; this is very different from what occurs during inanition, then the nitrogenous output may be twice that of the normal; the increase is not so marked when fat is given as during absolute abstinence from food; carbohydrate food lessens the increase still more. W. D. H.

Phloridzin Diabetes. By E. KÜLZ and A. E. WRIGHT (*Zeit. Biol.*, **27**, 181—214).—J. v. Mering, in his researches on this subject (see preceding abstract), has administered phloridzin to animals after varying periods of inanition. He believes that these periods are sufficiently long to enable the animal to get rid of all its glycogen, and as the amount of sugar in the urine is greater than that derivable from the drug, concludes that the source of the sugar must in these cases be, for the greater part, the proteïds of the body. Although in his last published papers, v. Mering admits the presence of a small amount of glycogen in the animals killed after phloridzin poisoning, he does not consider that this is sufficient to cause him to alter his original conclusions. The present research, undertaken before the appearance of v. Mering's last paper, had for its chief object the ascertaining of the fact whether the animals, after long abstinence from food and dosing with phloridzin, are absolutely glycogen free. It was found that they were not; the quantity of glycogen, especially in the muscles, being so great as in the author's opinion to considerably invalidate v. Mering's position. A large number of experiments on different species of animals are recorded with great fulness, and analytical details are succinctly tabled.

Minor points to be noted are the facts that phloretin (except in hens) causes diabetes, though not so powerfully as phloridzin; and that frogs do not suffer from glycosuria after the administration of either drug.

The paper concludes with some polemical remarks regarding the method of glycogen estimation used by v. Mering. W. D. H.

Chemistry of Vegetable Physiology and Agriculture.

Silicic Acid as a Culture Medium for Organisms. By W. Kühne (*Zeit. Biol.*, **27**, 172—179).—Silicic acid prepared from water glass by the addition of hydrochloric acid, and dialysed until free from acid and sodium chloride, coagulates after a time, especially on the addition of sodium chloride. The solution found best for the purpose was one of sp. gr. 1·02, containing 3·4 per cent. of anhydrous silicic acid. After a few days, this sets to a clear, transparent jelly. This mixed with nutritive substances (meat extract, deuteroalbumose, &c.), and sterilised by heating in metallic vessels at 160—170°, is recommended as a culture medium for micro-organisms. W. D. H.

Occurrence of Boron in the Vegetable Kingdom and its Physiological Meaning. By E. Hotter (*Landw. Versuchs-Stat.*, **37**, 437—458).—A large number of ashes of fruits, leaves, and twigs of fruit trees and portions of other plants were tested for boron. 1 to 1·5 grams of the ash was dissolved in 4 per cent. hydrochloric acid (10—15 c.c.) and tested with turmeric paper; if the result was uncertain or negative, a larger quantity of ash was tested with sulphuric acid and ethyl alcohol. Boric acid was found in the ashes of all the fruits which were examined; other ashes contained less.

In order to ascertain the physiological action of boron in plants, water-culture experiments were made with *Pisum sativum* and *Zea Maïs*. When much boron is taken up by the plant, the chlorophyll is destroyed, and consequently the process of assimilation stopped; and the root dies. When the amount of boron in the nutritive solution is increased, the plant becomes still less healthy; with 1 gram per litre the dry produce is very slight. Free boric acid is more prejudicial than the alkali salts. Different kinds of plants are differently affected by the same amount of boron; peas were much less able to resist its action than maize. The distribution of the boron was nearly equal in the healthy and unhealthy organs. N. H. J. M.

Composition of the Ash of Tobacco Leaves. By J. M. van Bemmelen (*Land. Versuchs-Stat.*, **37**, 409—436).—According to Nessler, Schloesing, and others, tobacco will burn well which is rich in organic potassium salts. Too much potassium nitrate is injurious; potassium chloride is also injurious, and calcium and magnesium chlorides still more so, owing to their fusibility and the consequent encasing of unburnt organic matter. Of organic substances, too much fat and too much albumin neutralise the good effect of organic potassium salts. It is of importance that the albuminoids and carbohydrates should be sufficiently decomposed in the curing.

Ash analyses are given of tobacco from Java, Mexico, Japan, Hungary, and Virginia. The results show that leaves of the best quality contain 12 to 15 per cent. of mineral matter (silica excluded), not much chlorine and sulphuric acid, no soda, or very little, and much potash, lime, and magnesia in combination with organic acids; that in the ash, not only the relation between the carbonates and the chlorides and sulphates ($CO_2 : Cl + SO_3$) is high (not under 7), but also that the relation between the potash and chlorides and sulphates ($K : Cl + SO_3$) is not under 2.

Tobacco which burns badly either contains an excess of chlorine and sulphuric acid over the amount of potash, or else the amount of potassium, compared with that of chlorine and sulphuric acid, is low, owing to the potash being partially replaced by soda. It is important to determine how far lime may replace potash. The total amount of ash in the best tobacco of different countries varies only slightly, and as the amount of chlorine, sulphuric acid, and soda is small, it is not improbable that lime, magnesia, and potash, as organic salts, can replace one another within certain limits. N. H. J. M.

Loss of Nitrogen in Acid Fodders. By F. W. WOLL (*Landw. Versuchs-Stat.*, **37**, 466—469).—A reply to Kellner and Sawano (this vol., p. 546). Although acid clover and other Leguminosæ lose nitrogen by dissociation of ammonium salts in drying, it has been shown that such a loss either does not take place at all, or is only very slight in the case of the acid fodders poorer in nitrogen, as for instance, green maize. In this case, the loss of nitrogen is due to the action of ferments. N. H. J. M.

Composition of Soils. By J. M. VAN BEMMELEN (*Landw. Versuchs-Stat.*, **37**, 347—373; compare this vol., pp. 822, 823, 832).—In the soils examined by the author, namely, sea mud, arable land, and volcanic arable land (Sumatra and Java), it was found that the amount of humus in relation to that of the clay, was greatest in freshly deposited mud; the heavy clay contained 30 per cent. of silica and alumina, and 6·9 per cent. of humus; the lighter clay, 17 per cent. of silica, and 3·2 per cent of humus. The percentage of nitrogen in humus varied from 4·5 to 7 per cent. The humus contains absorbed mineral matter, especially alkaline bases, which are of considerable importance for the fertility of the soil. The fertility of soil also depends on the state of humification of the organic matter. Pitsch's experiments (*Landw. Versuchs-Stat.*, **26**, 1) show that Grandeau's conclusions with regard to his so-called *matière noire* were erroneous.

The volcanic clay contained more colloidal silicates than ordinary clay, and was also more readily decomposed by hydrochloric acid and by dilute aqueous potash. Ordinary clay contains more silicates decomposable by sulphuric acid.

With regard to the alkaline bases in the colloïdal silicates and humates, it is suggested that the lime in the silicate is only in the most readily soluble portion; or else that dilute hydrochloric acid can extract lime from the colloïdal silicates without decomposing them. The amount of potash is greater in sea and river clay than in volcanic clay. The heavy sea clay contained 1 per cent. of potash; the lighter clay 0·4 per cent. Magnesia is less strongly combined in the colloid silicates and humates than potash, but more strongly than lime.

The percentage of phosphoric acid (soluble in nitric acid) in manured or unmanured arable land is generally between 0·25 and 0·10, except when the soil contains much chalk or sand, when it may be only 0·05. N. H. J. M.

Causes of Fertility of the Forest-land of Deli (Sumatra) and Java for Tobacco, and of the Decrease of Fertility. By J. M. VAN BEMMELEN (*Landw. Versuchs-Stat.*, **37**, 374—408).—The causes of the fertility for tobacco of the volcanic clay of Deli are the fresh forest soil, its loose texture, the amount of humus it contains, and probably also the basic composition of the silicates. The frequency of rain during the period of growth of the tobacco plant is also favourable. The cause of decrease of fertillity, which does not seem to be due to exhaustion of the soil, requires investigation. The crops are still sufficiently large, but the quality of the leaves is inferior. It is suggested that the composition of the humus has changed, and that the soil has lost its looseness of texture. The author suggests that the fertility might be restored by occasionally re-establishing the forests for a time. N. H. J. M.

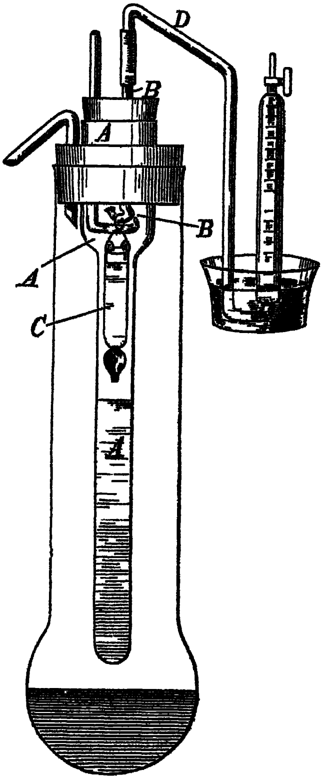
Loss of Nitrogen during the Fermentation of Nitrogenous Organic Matters and the Means for its Prevention. By H. v. KRAUSE (*Chem. Centr.*, 1890, i, 1065—1066; from *Journ. Landwirthschaft*, **38**, 1–68).—The decomposition and loss of nitrogen sustained by cow-dung was investigated, and the effect of the addition of several substances was determined. Superphosphate added in quantities of from 0·5 to 5·0 per 100 of the dung, proved to be an excellent means of preventing decomposition. Similar quantities of "superphosphate-gypsum" appear to assist rather than to retard the decomposition, but it nevertheless possesses considerable retentive power for ammonia.

Additions of kainite, from 0·5 to 15·0 per 100 of dung, assisted materially in preventing loss of ammonia when the dung was allowed to lie for short periods of time only; when kept in heap for protracted periods, considerable losses of ammonia, however, took place. Peat, when used in quantities from 0·5 to 10·0 per 100 of the dung, assists the decomposition, and considerable loss of nitrogen occurred. When added in much larger quantities, its power of absorbing ammonia becomes of value, and is useful where the urine is allowed to remain with the solid excrements. The addition of "basic phosphate" assisted the fermentations, and a very considerable loss of ammonia occurred. Lastly, experiment showed the importance of keeping the air from the dung, and that consequently less loss of ammonia occurs in the case of the dung being allowed to accumulate in the stalls than when it is regularly removed to a separate dung-heap.

J. W. L.

Analytical Chemistry.

Apparatus for the Estimation of Nitrogen in Ammonium Salts. By W. Hentschel (*Ber.*, **23**, 2402—2403).—The method is based on the decomposition of ammonium salts by sodium hypobromite. The apparatus consists of an outer vessel similar to those employed in V. Meyer's vapour density apparatus, it contains a small quantity of methyl alcohol, and is closed by a rubber stopper,



through this passes a short bent tube, the ends of which are cut at an acute angle. The inner vessel AA contains the sodium hypobromite solution, and is closed by a doubly bored rubber stopper. The delivery tube BB is bent at one end into a hook, on which is suspended, by a piece of platinum wire, the tube C; this tube contains a little mercury and a weighed quantity of the ammonium compound under examination. Through the second hole of the stopper, a bent glass rod passes easily, so that it may be freely turned. D is a capillary tube. The details of working are as follows:—The apparatus is heated by boiling the alcohol for about half an hour; when bubbles cease to appear at D, the tube C is released by means of the bent rod, and allowed to drop into the liquid in AA. An immediate evolution of nitrogen takes place, which displaces an equal volume ot air; the reaction is completed in a few minutes. No special correction is needed in measuring the mixture of air and nitrogen.

J. B. T.

Source of Error in the Estimation of Sulphuric Acid. By E. v. Meyer (*J. pr. Chem.* [2], **42**, 270).—The author points out that in the evaporation of large quantities of liquids on the waterbath, a not inappreciable amount of sulphuric acid may be absorbed from the gases given off by the combustion of the coal-gas used for heating, which is never free from sulphur. Experiments made with distilled water free from sulphuric acid showed that in evaporating 2 litres in a porcelain basin to 50 c.c. (which occupied six hours), an amount of sulphuric acid equal to 0·01462 gram SO_3 was absorbed. In another experiment 1 litre of pure water was evaporated in a platinum basin over a small Bunsen flame to 50 c.c. (the time occupied being 12 hours); in this case the amount of sulphuric acid found corresponded with 0·0106 gram SO_3. H. G. C.

Oxidation of Sulphides by the Electric Current. By E. F. Smith (*Ber.*, **23**, 2276—2283).—The substance to be examined was fused with caustic potash in a nickel crucible, which was connected with one end of an electric circuit, whilst a platinum wire dipping into the fused mass was connected with the other. In the circuit were also interposed an ammeter, for measuring the strength of the current, an apparatus for reversing the direction of the current, and a variable resistance. Rather more than 0·1 gram of the substance was generally used with 20—40 grams of caustic potash, and the current was allowed to run for 10 to 20 minutes, at a strength of 1—2 ampères; it was often found advantageous to reverse the current occasionally. The crucible and its contents were finally treated with water, the solution filtered from insoluble oxide, acidified, and the sulphuric acid in it estimated in the usual manner. It was found that in the case of blende, ZnS; cinnabar, HgS; galena, PbS; silverglance, Ag_2S; molybdenum-glance, MoS_2; stibnite, Sb_2S_3; orpiment, As_2S_3; jamesonite, $Sb_2S_5Pb_2$; enargite, AsS_4Cu_3; stephanite, $Sb_2S_8Ag_{10}$; kobellite, $(BiSb)_2S_6Pb_3$; fahlerz, $(SbAs)_2S_7(Cu_2Hg_2FeZn)_4$; tin pyrites, SnS_4Cu_2Fe; pyrrhotite, $Fe_{11}S_{12}$; and marcasite, FeS_2, all the sulphur was oxidised to sulphuric acid by treatment in the manner described above, but not more than half the sulphur in copper-glance,

Cu_2S, could be thus oxidised, while to effect the complete oxidation of iron pyrites, FeS_2, it was found necessary to add an equal weight of copper oxide, and use a current of 4 ampères. C. F. B.

Blowpipe Test for Mercury. By T. Charlton (*Chem. News*, **62**, 41—42).—After the sublimate is obtained in Johnstone's method for testing for mercury (Abstr., 1889, 797), the author recommends dropping a little iodine into the tube; when volatilised, this immediately gives the characteristic mercuric iodide if any mercury is present, whilst the inconvenience caused by the washing away of sublimate by the use of acid is obviated. D. A. L.

Reactions of Arsenic. By G. Loof (*Chem. Centr.*, 1890, i, 1078—1079; from *Apotheker Zeitung*, **5**, 263).—The author recommends hypophosphorous acid as the best reagent for arsenic, as described by J. Thiele (this vol., p. 1193). Arsenic is only precipitated from the strongly hydrochloric acid solution by heating. 10 c.c. of hydrochloric acid, if heated for several hours with 0·1—0·2 gram of calcium hypophosphite, will show the presence of arsenious oxide if 0·01 milligram be present. Of glycerol, sulphuric acid, phosphoric acid, 5 c.c. with 10 c.c. of concentrated hydrochloric acid is a suitable quantity; of calcium phosphate, sodium phosphate, or tartar emetic, 0·5 gram in 10 c.c. of hydrochloric acid, is sufficient. In the case of bismuth subnitrate, it should be previously freed from nitric acid by gentle heating, or by dissolving an equal weight of the hypophosphite with it in hydrochloric acid. Of *liq. ferri sesq.* 5 c.c. in 10 c.c. of hydrochloric acid is decolorised with Bettendorf's reagent, and then 0·2 gram of the hypophosphite added. Antimony oxysulphide is dissolved by hydrochloric acid and potassium chlorate, filtered through glass wool, and heated with hypophosphite for several hours on the water-bath. J. W. L.

Quantitative Estimation of Vanadium and the Separation of Vanadic Acid from Phosphoric Acid. By R. Holverscheit (*Inaugural Dissertation*, *Chem. Centr.*, 1890, i, 977—978).—By the application of Rosenheim's iodometric method (*Annalen*, **251**, 197), the author finds that vanadic acid may be rapidly and exactly determined, after first precipitating it as barium or lead vanadate. The substance is dissolved, and the vanadic acid precipitated with barium chloride or lead acetate. The precipitate is boiled with hydrochloric acid and potassium bromide, and the liberated bromine determined volumetrically with potassium iodide. In the absence of substances, such as molybdic acid, which are reduced by sulphurous acid or hydrogen sulphide, the vanadic acid may also be determined by first reducing it with one of these agents, the excess being then boiled off, and the vanadium tetroxide determined by potassium permanganate. If the vanadic acid has been precipitated as barium or lead vanadate, the metal must first be separated before titrating with potassium permanganate. For the determination of vanadic acid and phosphoric acid when they occur together, the vanadic acid is first reduced to tetroxide with sulphurous acid, and after expelling the excess of the latter, the phosphoric acid may be precipitated with molybdic acid and filtered off. If the amount of vanadic acid is large, the precipitation of the phosphoric acid should be executed rapidly at 55—60°, using a considerable excess of molybdic acid; or the vanadic acid may first be determined in the solution by boiling with hydrochloric acid and potassium bromide, the liberated bromine being then determined volumetrically; the phosphoric acid is determined by evaporating the solution with a little sulphuric acid to dryness, the residue is taken up with water, the vanadic acid reduced with sulphurous acid, and the phosphoric acid precipitated with molybdic acid, as above described. If the alkalis are to be determined, the substance, dissolved in acetic acid, is treated, at boiling heat, with lead acetate, and the lead vanadate filtered off, the alkalis being then determined in the filtrate. J. W. L.

Detection and Estimation of Lactic and Butyric Acids in Wines. By E. Mach and K. Portele (*Landw. Versuchs-Stat.*, **37**, 305—323).—Owing to heavy rainfalls and consequent flooding of wine-districts in South Tyrol, the grapes often become covered with a thin crust of mud. This contains, besides clay, a considerable amount of calcium and magnesium carbonates, which neutralise much of the acid of the grapes, and give rise to lactic and butyric fermentation. The resulting wine blackened when exposed to air, and could only be used for making inferior brandy. The mud-crust may, however, be almost entirely removed by immersing the grapes for a few minutes in 2 or 3 per cent. sulphuric acid; they are afterwards washed in running water. Determinations of alcohol, total acid, volatile acids, potassium hydrogen tartrate, glycerol, ash, and ash constituents were made at different periods, in samples of wine prepared (*a*) after washing the grapes with acid; (*b*) without washing the grapes, and letting the must ferment with the skins; (*c*) same as (*b*), but the must was drawn off, allowed to settle, and again drawn off; (*d*) same as (*c*), but the must was treated with sulphuric acid (1·83 grams per litre). The results of the analyses are given in tables. Acetic, butyric, and lactic acids were determined in samples (*a*), (*b*), and (*c*). The results show that the wine prepared from the grapes washed with acid was free from butyric and lactic acids, whilst the greater part of the small amount of acid in (*b*) consists of lactic acid.

Detection and Estimation of Butyric Acid in Presence of Acetic Acid.—500 c.c. of wine is distilled until 125 c.c. remains; the residue is diluted to its original bulk, and again distilled until 125 c.c. remains. This is repeated four times, and the free acid in the united distillates determined by titration with soda or with baryta. If soda has been used, the neutralised distillate is evaporated down, treated with dilute sulphuric acid, and steam distilled, and the distillate neutralised with baryta. The solution is so far evaporated down that it will solidify when cold, after which it is treated with absolute alcohol (10 parts). The barium butyrate dissolves, whilst the acetate remains almost entirely undissolved. The salts are separated by filtration and washing with absolute alcohol. The aqueous solutions of the salts are treated with sulphuric acid, steam distilled, and the acid determined by titration with soda. In order to ascertain whether the separation was complete, the neutralised solutions are evaporated down and treated with alcohol and sulphuric acid; a trace of impurity is easily detected by the odour of ethyl salt.

Detection and Estimation of Lactic Acid.—500 c.c. of wine is just neutralised with soda, some pumice powder added, and the whole evaporated to dryness in a deep dish on a water-bath, with frequent stirring. The residue is rubbed in a mortar, moistened with dilute sulphuric acid, and shaken three times with ether (200 c.c.). The united ether extracts are carefully evaporated down in an Erlenmeyer flask, the residue washed with water into a deep dish, treated with an equal volume of alcohol, and slightly heated for a long time with freshly precipitated lead carbonate, until effervescence ceases. It is then digested for three or four hours, filtered, and washed with 95 per cent. alcohol. The filtrate is decomposed by hydrogen sulphide, filtered, heated on a water-bath to remove excess of hydrogen sulphide, and distilled until one quarter remains. It is then diluted to its original bulk and again distilled, and this is repeated until the distillate is neutralised by not more than 0·5 c.c. of normal soda solution. The lactic acid in the residue is determined by titration. The results thus obtained are too high, owing to the presence of malic acid. The neutralised solution is therefore evaporated to dryness, and the sodium lactate dissolved out by absolute alcohol (sodium malate being insoluble). After evaporation of the alcohol, the residue is treated with dilute sulphuric acid, and extracted three times with ether. The residue from the ether is digested with lead carbonate, and the acid afterwards liberated as before. The solution of acid is divided into two parts, the one being used for the titration, and the other converted into zinc salt, to determine its purity.

Palm's method (Abstr., 1887, 307) was tried, and although it answered well for the detection of lactic acid, it was found to be unsatisfactory as a quantitative method. N. H. J. M.

Quantitative Estimation of Uric Acid in Human Urine. By W. Camerer (*Zeit. Biol.*, 27, 153—171).—The method adopted for the estimation of uric acid consists in estimating the nitrogen in the precipitate of uric acid produced by silver nitrate (Abstr., 1889, 1040); Salkowski and after him Ludwig, however, decompose the precipitate produced by silver nitrate with sulphuretted hydrogen or sodium sulphide and weigh the uric acid as such. Camerer's simpler method has certain disadvantages. Some authors have stated that a loss of uric acid is unavoidable; this is found to be more marked in urines than in solutions of pure uric acid; it is independent of the concentration, and is apparently due to imperfect filtering; it was found that the error was so small as to be negligible, if Schleicher and Schull's filters were used. Another objection is that silver nitrate precipitates from urine not only uric acid, but certain substances of the xanthine group. A number of comparative experiments were therefore made, the uric acid being estimated both by the author's method and by Ludwig's method. The latter was found to be by no means a simple process, and the difficulties are pointed out and improvements in the methods of filtration, &c., suggested. The results in two analyses by the two methods were identical; in the remaining nineteen analyses, Ludwig's method gave the lower result, the percentage difference varying from 5·9 to 16·7, the mean being 10·9. In order to avoid the lengthy and troublesome method proposed by Ludwig, it is recommended that the quantity of uric acid present be calculated from the quantity as found by the author's method, as in the following example: The silver precipitate of 150 c.c. of the diluted urine yielded 14·39 milligrams of nitrogen, or 9·6 per 100 c.c. 9·6 × 3 = 28·8 = the quantity of uric acid by Camerer's method. The quantity found by Ludwig's method was 26·0. Taking the mean percentage difference as 11 instead of 10·9, the true amount of uric acid can be calculated from Camerer's number, thus—28·10 − (28·8 × 0·11) = 25·6, which is nearly the same number as that obtained by direct analysis. If several analyses be made, and the mean taken, the results as shown in a table are practically identical in those obtained by calculation and by experiment.

The physiological deductions from the experiments recorded coincide very closely with those of Schultze (this vol., p. 280), the following being the average numbers obtained from patients suffering from gout:—

Diet.	Urea nitrogen.	Uric acid nitrogen.	Total nitrogen.	Uric acid nitrogen.
Mixed diet with alcohol.	100	2·36	100	1·5
Mixed diet with mineral water instead of alcohol	100	1·9	100	1·2

Some analyses are also given of the urine from three patients suffering from febrile complaints; the most marked point noted appears to be the large quantity of xanthine compounds excreted; that is the difference in the uric acid by Ludwig's method, and that by the author's method is greater than the normal mean.

W. D. H.

Estimation of Fat in Milk in Dairies. By O. LANGKOPF (*Chem. Centr.*, 1890, i, 981—982; from *Pharm. Zeit.*, 35, 225).—The author recommends the Soxhlet's method by means of the areometer, and that of de Laval by means of the lactocrite. The latter is carried out as follows: 10 c.c. of milk is heated with 10 c.c. of a mixture of acetic acid (95 vols.) and sulphuric acid (5 vols.) in a test tube on the water-bath for 7—8 minutes. The test tube is closed by an india-rubber stopper carrying a glass tube 20 cm. long. By this means the caseïn is completely dissolved and the fat floats to the surface. The whole of the contents of the test tube are transferred to a small metal capsule, into which is then pushed a glass tube, so wide at the base that it exactly fits into the capsule, the liquid contents being thus forced up into the glass tube. The latter is thick walled, having but a narrow bore, and the column of liquid thus becomes a long one; it is also graduated in such a manner that each division is equivalent to one-tenth per cent. of butter fat. For the better separation of the separated fat, these tubes are fixed into a centrifugal apparatus, which is worked for ten minutes at a rate of 6000—7000 revolutions per minute. J. W. L.

Examination of Oils, Fats, &c. By T. T. P. B. WARREN (*Chem. News.*, 62, 27—28, 51, and 75).—These substances may, according to the author, be divided into three classes as regards their behaviour with sulphur chloride:—Those which are not acted on, those which yield a magma completely soluble in carbon bisulphide, and those which yield a magma only partially soluble in that solvent. When the sulphur chloride acts, hydrogen chloride is evolved, and the sulphur combines with the oil residue.

Animal, fish, and solid vegetable oils and fats, and also the fatty acids of fluid vegetable oils, do not yield products with sulphur chloride insoluble in carbon bisulphide, but the fluid vegetable oils do, and therefore the latter can be readily separated from the former by this means. The proportion of insoluble magma produced from a fluid vegetable oil is reduced by oxidation and therefore by treatment with ozonised air, or by keeeping in air, or by hot pressing as compared with cold extraction, &c. Therefore the more readily oxidisable oils can be separated from the less readily oxidisable oils by treatment first with ozonised air, then with sulphur chloride, then with carbon bisulphide. Olive oil is the most stable oil as regards oxidation; whilst oils such as poppy, walnut, linseed, rape, and cotton oil oxidise rapidly, with the result (besides the diminution in the amount of the insoluble magma) that their viscosity is increased and their iodine absorption reduced, which may be estimated and taken as a measure of the oxidation. Sulphur chloride has comparatively little effect either on the weight or on the iodine absorption of the indifferent oil and fats. The total weight of magma should be ascertained in all cases.

As an example of a separation on the author's plan:—An olive oil adulterated with lard and cotton-seed oil would, after treatment with sulphur chloride, yield the lard oil to carbon bisulphide; but both the lard oil and the altered cotton-seed oil would be removed by this solvent by treating the adulterated olive oil first with ozonised air and then with sulphur chloride. Lubricating lard oil compounded of animal fat and cotton-seed oil, or of cotton-seed stearin and animal fat, or oleomargarin adulterated with cotton-seed olein, can be separated and detected. The action of sulphur chloride on the oils attacked by it is modified in mixtures of such oils, inasmuch as the more susceptible oil interferes with the action on the other; in mixtures of castor and rape oils for instance, the former absorbs most of the sulphur chloride, leaving much of the latter oil unattacked. The author points out that the oleic and stearic acids separated from oils, &c., behaving differently with sulphur chloride, when reconverted into glycerides, yield products having the same distinctive characteristics as the original oils or fats; which seems to indicate a chemical difference in these oleic and stearic acids.

Iodine tests must be made with great uniformity, should proceed for 24 hours at the same temperature in a warm dark room with precautions against the escape of iodine or other volatile matter. Hubl's reagent is most safely made up as required. D. A. L.

Colorimetric Method for Estimating Tannin in Barks. By S. J. Hinsdale (*Chem. News*, **62**, 19).—Material containing 1·5 to 10 per cent. of tannin is used in quantities of 0·8 gram per 500 c.c. of water, and five drops of the extract is treated with 5 c.c. of a mixture of 0·04 gram potassium ferricyanide and 1·5 c.c. of *liquor ferri chloridi* solution in 500 c.c. of water; after a minute, 20 c.c. of water is added, and within three minutes the colour is compared with that produced simultaneously and under exactly similar circumstances from a definite number of drops of a standard solution containing 0·04 gram of pure tannin in 500 c.c. of water; then the number of drops of the standard producing the same shade, correspond with the percentage of tannin present in the material. To avoid extremes in shades, extracts of materials containing more than 10 per cent. are made more dilute, and those with less than 1·5 per cent. stronger.

D. A. L.

Estimation of Tannin by means of Iodine. By A. Moullade (*J. Pharm.* [5], **22**, 153—159).—Carbon bisulphide is used as indicator in place of starch, and it is necessary to standardise the solution of iodine, and to make the assays under similar conditions. The iodine solution may contain 5·20 grams of iodine and 7·6 grams of potassium iodide per litre; this is standardised by means of a recently-prepared solution of pure and dry tannin, 1·0 : 1000 water; a 10 per cent. solution of hydrogen sodium carbonate is also required. 10 c.c. of tannin solution, about 20 c.c. of the sodium carbonate solution, 10 c.c. of water, and 2 to 3 c.c. of carbon bisulphide are placed in a flask and iodine solution is run in until the last drop gives a violet or rose tint to the bisulphide. If 10·5 c.c. of iodine has been used, a second assay is made, in which 10 c.c. is run in at once; if this is not sufficient, a third assay is made, running in 10·3 c.c., which gives the colour, say; then a fourth assay, using 10·2 c.c., and giving no colour, indicates that 10·3 c.c. of iodine measures 10 c.c. of the tannin solution. The astringent substances to be assayed are treated in the same way, and their contents in astringent acids can be expressed in terms of pure tannin. The assay should not contain more than 1·5 grams of tannin per litre. To 10 c.c. of the solution, 30 c.c. of the sodium carbonate solution is added, the 10 c.c. in excess being employed to largely saturate the astringent acids present, and the titration is made directly without filtration. To ascertain the real amount of tannin in a solution, the assay is repeated on another portion from which the tannin has been removed by treatment with skin. The method is applicable to all astringent substances, even to wine. In the case of wine, all interfering compounds are practically eliminated as follows:—The assay is first made on 10 c.c. of the wine; then 50 c.c. of the wine is mixed with 50 c.c. of a solution of gelatin (1 : 1000), and 20 c.c. of the filtrate is taken for a new assay. The difference between the volumes of iodine required in the two cases measures the tannin in the wine. J. T.

Colorimetric Method for Estimating Morphine in Opium Preparations. By S. J. Hinsdale (*Chem. News*, 62, 77—78).—Various dilutions of officinal opium tincture with alcohol, 3 : 1, 2 : 2, 1 : 3, are prepared, and a single drop of each is treated with about 5 c.c. of fresh ferricyanide mixture (0·04 gram of potassium ferricyanide, 1·5 c c. of *liquor ferri chloridi*, 500 c.c. of water), in about a minute 15 or 20 c.c. of water is added, and the colour observed; for examination, opium preparations are treated in a similar manner, and the shade produced compared with the standard. D. A. L.

Determination of Morphine in Opium. By G. Loof (*Chem. Centr.*, 1890, i, 1082; from *Apotheker Zeitung*, 5, 271).—The author recommends the following method:—5 grams of the finely-ground opium is carefully rubbed with water and diluted to 78 c.c. At the end of 1 to 2 hours, during which the mixture is shaken frequently, 60·8 c.c., corresponding with 4 grams opium, is filtered off, 0·2 gram of oxalic acid is added, and at the end of half-an-hour, 5·2 c.c. of potash (1 : 2) is added, the mixture well shaken, and 16·5 c c. filtered through a dry filter into an Erlenmeyer flask of 30 c.c. capacity, this quantity corresponding with 1 gram of opium, 5 grams of ether, free from alcohol, is added, and the mixture shaken briskly for 10 minutes in the closed flask. The excess of ether is volatilised by blowing a current of air into the flask, after which the separated morphine is collected on a filter, and washed with water saturated with ether. The morphine on the dried filter may be transferred back to the portion remaining in the flask, and the weight of the whole obtained by drying until the weight of the flask and contents is constant. In the case of tincture of opium, 50 c.c. is used for each experiment, and of opium extract 2·5 grams is a suitable quantity, the remaining operations being the same as above described. J. W. L.

Testing Acetanilide. By E. Ritsert (*J. Pharm.* [5], 22, 21—23; from *Pharm. Zeit.*, 35, 306).—After drying for two hours at 105°, the melting point should be 114°. This may be raised or lowered by the presence of acetotoluidides. The following are tests for pure acetanilide:—0·1 gram is boiled by portions in 2 c.c. of concentrated hydrochloric acid; after cooling and the addition of one or two drops of chlorine-water, the liquid takes a beautiful blue tint. The aqueous solution of acetanilide should not have an acid reaction; on boiling the solution and adding a few drops of ferric chloride solution, a deep reddish-brown colour should be produced; this disappears on adding a mineral acid. If to a boiling aqueous solution of acetanilide (1 : 30) a drop of potassium permanganate solution (0·1 : 100) is added, the rose colour ought to persist five minutes at least, and should not become yellow on boiling afresh. Finally, the acetanilide should leave no solid residue when heated to redness. J. T.

Estimation of Pyridine Bases in Gas-liquor. By W. Kinzel (*Chem. Centr.*, 1890, i, 946; from *Pharm. Centralhalle*, 31, 239—242). —The author bases his method on the fact that pyridine mercuric chloride is completely decomposed into pyridine and mercuric chloride by boiling the aqueous solution for some time, the pyridine being precipitated. The mercurammonium chloride which, in the case of gas-liquors, would be formed at the same time is much more stable, becoming slowly converted into basic mercury compounds and ammonium chloride. J. W. L.

New Reactions of Albumins. By C. Reichl (*Monatsh.*, **11**, 155—165).—The author has previously (Abstr., 1889, 1092) called attention to the colour reactions obtained by treating the albuminoïds with alcoholic benzaldehyde or salicylaldehyde in presence of dilute sulphuric acid and ferric sulphate, and has now elaborated his previous experiments and extended them to other aromatic aldehydes.

Reaction with Benzaldehyde.—The blue condensation-product obtained on mixing egg-albumin, benzaldehyde, dilute sulphuric acid, and ferric sulphate, gives an absorption-band in the spectrum near D; apparently it is a compound of a base with sulphuric acid, for, on adding an alkali to the solution, the blue colour disappears with formation of a brownish-white precipitate, which dissolves in acids, again forming a blue or bluish-green solution. The precipitate dissolves in alkalis, yielding a yellow solution. The ferric sulphate plays the part of an oxidising agent, since dilute nitric acid, mercuric oxide, and other substances which readily part with their oxygen, may be substituted for it. This reaction of albumin appears to be due to the scatole-group contained in it, since scatole itself gives a bluish-violet coloration when similarly treated.

Reaction with Salicylaldehyde.—When the solid albuminoïd is moistened with a 0·5 per cent. alcoholic solution of salicylaldehyde, the alcohol allowed to evaporate, and the substance treated with a little dilute sulphuric acid containing ferric sulphate, coloured products are formed. Egg-albumin and blood-albumin, blood-fibrin, and casein give a bluish-violet; legumin, a brownish-violet; vegetable fibrin, a brownish-yellow; and sheep's-wool and skin, violet-blue compounds. After some time, the solid mass dissolves, forming a solution having the same colour. The bluish-violet solution obtained from egg-albumin shows an absorption-band in the spectrum between C and D, and contains a base which may be precipitated by alkalis. In order to recognise albumin in solution by this test, the liquid is mixed with a drop of the alcoholic solution of the aldehyde, an equal volume of concentrated sulphuric acid added, cooled, without shaking, and finally a few drops of ferric sulphate are poured in. According to the strength of the solution, a blue or violet zone is sooner or later formed. Salicylaldehyde gives a similar blue or violet solution when treated with scatole. The oil from *Spiræa ulmaria* gives the same reactions with the albuminoids as salicylaldehyde, but the colour is not so intense.

Reaction with Anisaldehyde.—Egg-albumin, vegetable-albumin and caseïn give a violet coloration; blood-albumin and sheep's-wool, a violet-red; blood-fibrin, a blue; legumin, a brownish-violet coloration. The violet solution from egg-albumin gives an absorption-band between D and F. Alkalis precipitate a base which is apparently a scatole compound.

Reaction with Vanillin, Piperonal, Cinnamaldehyde, and Furfuraldehyde.—All these substances give coloured products with the albuminoids and similarly coloured products with scatole.

The aromatic aldehydes, in presence of sulphuric acid and ferric sulphate, give coloured condensation-products with phenols, but these have an acid character, and unite with bases to form new coloured compounds It consequently follows that in albumin it is the scatole-group which furnishes the coloured compounds above described. The production of these substances forms not only a very delicate test for albumin, but may be used conversely as a test for the presence of aldehydic compounds in wood, in resins, and in ethereal oils. G. T. M.

Analysis of Peptones. By G. Bruylants (*Chem. Centr.*, 1890, i, 1084; from *Revue Internal. Scientif*, 3, 167)—*Insoluble nitrogenous substances:* 6 grams of the substance is treated with water, diluted to 500 c c, allowed to settle for two days, the clear liquid decanted, the insoluble portion washed by decantation, and weighed on a tared filter after drying at 105°. *Coagulable albumin:* 10 grams of the substance is treated with 300 c.c. of water, and, after clearing, 150 c.c. is filtered off and heated to boiling. The precipitated albumin is washed by decantation and weighed on a tared filter, after drying at 105°. *Albumose:* 5 grams of the substance is boiled in 200 c.c. of water, filtered, and 100 c.c. of the filtrate is evaporated to about 10 c.c. and 100 c c. of a saturated solution of ammonium sulphate added. The precipitate obtained is washed with a cold saturated solution of ammonium sulphate, transferred to a tared filter, dried at 105°, and weighed. The adhering ammonium sulphate is then washed off with 500 c.c. of water, its amount determined by an estimation of the sulphuric acid, and the amount of precipitated albumin thus obtained by difference. For the nitrogen determinations, Kjeldahl's method is employed.

J. W. L.

Analysis of Peptones. By A. Denayer (*Chem. Centr*, 1890, i, 1084—1085; from *Revue Internal. Scientif.*, 3, 168).—The author considers the method of precipitating the albumose-peptone, as recommended by G. Bruylants (preceding abstract), inaccurate, since mucilage is precipitated by ammonium sulphate solution. He recommends the following method for the complete analysis of peptones:—*Mucilage:* 1—2 grams of peptone is treated with water and precipitated with Mayer's potassium mercury iodide solution (49 801 grams potassium iodide, 13·546 grams mercuric chloride, 1000 c.c. water), filtered, washed, concentrated to a few c c, saturated solution of ammonium sulphate added, and the mixture heated to boiling, whereby the mucilage is precipitated The precipitate is washed by decantation, then with ammonium sulphate, and, lastly, rapidly with cold water; the double iodide is separated with boiling alcohol, and the mucilage, with adhering ammonium sulphate, is weighed. The ammonium sulphate is determined, and its weight deducted. *Albumose peptone:* 1—2 grams of peptone is treated with 5 c.c. of water, the mucilage and albumose precipitated with ammonium sulphate, and the precipitate weighed, from which is deducted the weight of mucilage and ammonium sulphate. *Peptone:* 1—2 grams of substance is dried in a vacuum at 60°, whereby the substance swells up, and is then washed with 95 per cent. alcohol. The residue is dissolved in a few c.c. of water, and an excess of sodium phosphotungstate added. The precipitate, consisting of mucilage, albumose, and peptone, is weighed on a tared filter. It is then incinerated, and the weight of the ash, as also the weights of the mucilage and albumose, deducted from that of the whole precipitate, the difference being peptone. *Unchanged substances*, consisting of amido-bases, fatty acids, and amido-acids, are determined in the alcoholic extract. Taurine, dextrose, and glycogen are insoluble in alcohol, and are determined by the difference between the determined substances and 100. The water, mineral matters, and insoluble substance are determined according to Bruylants' method (*loc. cit.*). The author adds the following analyses:—

	Peptone from albumin of cleaned meat.	Peptone from egg-albumin.	Peptone prepared directly from meat.
Peptone	37·675	34·700	25·857
Albumose	31·300	53·350	15·964
Mucilage..............	—	—	9·826
Unchanged products.....	5·525	5·930	29 972
Mineral matters	8·285	1·025	19·386
Water	10·250	4·625	—
Insoluble	9·965	3·980	—

J. W. L.

Quantitative Estimation of Furfuraldehyde and of Pentaglucoses (Pentoses). By A. Günther and B. Tollens (*Ber.*, 23, 1751—1752).—The method of estimating furfuraldehyde by precipitating with ammonia as hydrofurfuramide does not yield very trustworthy results, and the authors propose instead to estimate it by titration with phenylhydrazine, employing aniline acetate as indicator, which gives results accurate to 1—2 per cent. They have also improved the process of distilling pentaglucoses (pentoses) with hydrochloric acid, so that the quantity of furfuraldehyde obtained is constant, and by estimating the latter they are therefore enabled to determine the quantity of pentaglucoses (pentoses) present.

Pure arabinose and xylose yield about 50 per cent.; cherry gum, 15 per cent.; gum arabic, 14 per cent.; and wheat and oat straw, 13 per cent. by weight of furfuraldehyde. On the other hand, starch and sugar only yield $\frac{1}{4}$—$\frac{1}{2}$ per cent., and ivory-nut shavings, about 1 per cent. Glycuronic acid, however, yields about 46 per cent.

H. G. C.

General and Physical Chemistry.

Dispersion of Carbon Compounds. By P. Barbier and L. Roux (*Compt. rend.*, **111**, 180—183; compare Abstr., 1889, 865, this vol., p 1034).—Measurements of the refractive and dispersive powers of simple and mixed ethers of the methane series show that the dispersive power and the specific dispersive power increase with the molecular weight, but are practically the same for all isomerides containing the same quantity of carbon. The introduction of CH_2 into the molecule raises the specific molecular dispersive power by about 8·2. In the equation $\left(\frac{B}{d} - b\right)M = a$, the value of a is −6·443, and of b +0·5790; in the equation $(B - \beta)\left(\frac{M}{d}\right)^{\frac{1}{3}} = K$, β = 0·6626 and K = −1·44.

In methyl allyl, ethyl allyl, and propyl allyl ethers, the dispersive power and specific dispersive power remain practically constant, and do not increase with the molecular weight. Comparing these ethers with others containing the same number of carbon atoms, it is seen that the dispersive power increases as the proportion of hydrogen diminishes.

In the case of methyl benzyl, ethyl benzyl, propyl benzyl, isobutyl benzyl, and amyl benzyl ethers, the dispersive power diminishes as the molecular weight increases, but the addition of CH_2 produces a variation in the specific molecular dispersion equal, as in the methane series, to about 8·2. For the series, in the first equation, a = +40·87, and b = +0·5834; in the second equation, β = 0, and K about 4·4.

In all cases the specific molecular dispersive power of the ethers is equal to the sum of the dispersive powers of the two alcohols from which they have been formed, minus the dispersive power of the water eliminated.

C. H. B.

Dispersive Power of Acids of the Acetic Series. By P. Barbier and L. Roux (*Compt. rend.*, **111**, 235—236).—The dispersive power of acids of the acetic series increases with their molecular weight. Formic acid is an exception, if the dispersive power B is alone considered, but the exception disappears in the case of the specific dispersive power. The dispersive powers of isomerides are practically the same, but the values are highest in the case of the normal acids. The differences between the successive values of the specific molecular dispersive powers are practically constant, and equal to 7·8, so that the variation of the specific dispersive power may be represented as a function of the molecular weight, thus, $\left(\frac{B}{d} - b\right)M = a$, in which a = −11,515, b = 0·5625. The relation between the dispersive power and the molecular volume is the same as in the case of the corresponding alcohols (this vol., p. 1034), the values of the constants being β = +0·6393, K = −1·08.

C. H. B.

Dichromate Cell. By GENDRON (*Dingl. polyt. J.*, **275**, 68—70).—This cell, in which potassium or sodium dichromate forms the depolarising fluid, is capable of yielding a powerful current for a lengthened period. The area of its electrodes is large in proportion to the capacity of the cell; the internal resistance is small, the electrodes being placed parallel, and as closely to one another as is practicable. The zinc plates are readily exchanged without the necessity of interrupting the current, the fluid can be kept at a constant level, whilst the spent liquor is removed from the lower part of the cell by the aid of an automatic arrangement of valves, full details and drawings being given in the original. D. B.

Theory of Secondary Batteries. By F. STREINTZ and G. NEUMANN (*Ann. Phys. Chem.* [2], **41**, 97—112).—Streintz, in a former paper (this vol., p. 315), showed the electromotive behaviour of the plates of a secondary cell on charging and discharging. The authors now endeavour to fix the chemical reactions which take place at the same time, and for this purpose investigate the difference of potential exhibited by various lead compounds with respect to an amalgamated zinc plate. The compound was pressed into two strong glass vessels, one provided with a platinum, the other with a bright lead electrode. The zinc plate was immersed in dilute sulphuric acid, and connection made with the substance by means of a woollen thread moistened with the acid. The lead or platinum electrode was connected with one pair, the zinc plate with the other pair of quadrants in a sensitive electrometer. When the same result was obtained with lead as with platinum, it was concluded that the conduction was metallic; when otherwise, electrolytic. The lead compounds investigated were the oxides Pb_2O, PbO, Pb_3O_4, PbO_2; the hydroxides $Pb(OH)_2$, $PbO(OH)_2$; and the sulphate. The peroxide was the only substance that showed metallic conduction, and in general the difference of potential against zinc increased in the case of the oxides and hydroxides with the quantity of oxygen they contained.

The authors formulate their conclusions as follows:—The phenomena in a secondary cell are sufficiently explained by the behaviour of metallic lead, its sulphate, and its peroxide, together with the gaseous ions, oxygen and hydrogen. On discharging, the metallic surface of the negative plate is converted into sulphate, which passes in part into peroxide; whilst the peroxide of the positive plate is superficially converted into sulphate. On charging, the sulphate disappears from both plates, and finally the negative plate consists entirely of lead and absorbed hydrogen, the positive plate of pure peroxide. (Compare Frankland, this vol., p. 842.) J. W.

Electrical Properties of Semi-permeable Walls. By W. OSTWALD (*Zeit. physikal. Chem.*, **6**, 71—82).—A semi-permeable material is looked on as one which allows the passage through it of the solvent, but not of the dissolved salt. The permeability of any given material does not, however, depend on the nature of any given salt as a whole, but on that of each of its ions. Ferrocyanide of copper is permeable by potassium chloride, because it allows the passage of both the potassium and chlorine ions, not by barium chloride, because it will not allow the passage of the barium, and not by potassium sulphate, because it will not allow the passage of the SO_4 ions.

If a solution the ions of which cannot pass through a semi-permeable material, be submitted to electrolysis, the electrodes being separated by a semi-permeable wall, the latter will itself act as a metallic electrode. Two glasses were filled with normal copper sulphate solution, and connected by a U-tube, the ends of which were covered with parchment paper. The U-tube was filled with normal potassium ferrocyanide, so that a layer of copper ferrocyanide formed on the paper, and a current was then passed from one glass to the other. After a time, copper was found deposited on the parchment paper in the glass which contained the positive electrode. The mechanism of the process appears to be that the positively-charged copper ions come in contact with the ferrocyanide film, through which they cannot pass, and therefore here give up their charges, and are deposited in the metallic state. The same thing happens to the negative $FeCy_6$ ions at the other side of the film. These, by loss of an equivalent of negative electricity, become converted into the triad ferricyanide ions. At the other film, the potassium ions, which can permeate the copper ferrocyanide, pass through and unite with the SO_4 ions of the copper sulphate, and so establish electrical equilibrium.

This view of the peculiar behaviour of semi-permeable materials towards different ions affords an explanation of the fact noticed by Becquerel that when a tube containing copper nitrate solution is placed in a solution of sodium sulphide, a deposition of copper takes place in the interior of the tube. In this case, the copper sulphide first formed allows the passage of the NO_3, but not of the copper ions. The NO_3 ions coming in contact with the sodium sulphide bring about the following change :—

$$\begin{array}{cccccccccc} 2NO_3 & + & 2Na_2 & S & = & 2Na & NO_3 & + & K_2 & S_2. \\ 2(-) & & 4(+) & 4(-) & & 2(+) & 2(-) & & 2(+) & 2(-). \end{array}$$

If the positive and negative charges are counted, it will be seen that there are six negative and four positive before, and four negative and four positive after the reaction. The negative charges set free combine with the positive charges of the copper ions on the other side of the film, and the metal is thus deposited.

The author shows that many electrophysiological phenomena are explained by the above facts with regard to semi-permeable materials, as that of the secondary resistance of albumin noticed by Dubois-Reymond (*Monatsber. Berl. Akad.*, 1860, 816). The fact that damp membranes may, under circumstances, act as perfect insulators is also thus explained. H. C.

Difference of Potential between two Dilute Solutions of Binary Electrolytes. By M. PLANCK (*Ann. Phys. Chem.* [2], **40**, 561—576).—In a former paper (this vol., p. 677), the author calculated the difference of potential for the case of two solutions containing the same electrolyte in different proportions. The integration of the differential equations for the general case of two solutions containing different electrolytes is the subject of this communication. The existence between the two solutions of a limiting layer of small but still finite thickness is assumed. Different values for the difference of potential are found according to the way in which the concentration is supposed to alter within the intermediate layer. The author shows, however, that in a very short time a state of stability will be reached in which the total concentration (sum of the concentrations of the positive or negative ions) will vary within the layer as a linear function of the distance. This consideration is sufficient to make the above problem uniquely soluble, supposing the electrolytes to be completely dissociated. A comparison of the calculated values for the difference of potential with Nernst's experimental numbers shows a satisfactory agreement. J. W.

Electrical Resistance of the Alloys of Ferro-manganese and Copper. By E. L. Nichols (*Amer. J. Sci.* [3], **39**, 471—477).—The resistance of alloys of ferro-manganese and copper was determined at 20° and 100°, the object being to investigate the change of resistance with change of temperature between these limits. In the course of these experiments, it was found that a number of the alloys had the remarkable property of decreasing in resistance each time that they were subjected to a change of temperature, an alloy containing 80·82 per cent. of copper and 19·12 per cent. of ferro-manganese, when heated and cooled through the above range of 80°, diminishing in resistance with each operation, the diminution being still perceptible at the end of the seventh cycle. On being then raised to a red heat and allowed to cool, a still more marked diminution in the resistance of the above alloy was found to have taken place. The temperature coefficient of this alloy was positive, and continued to increase as the heating and cooling process was repeated. With an alloy consisting of 70·65 parts of copper and 29·35 parts of ferro-manganese, a similar behaviour was observed. After being brought into a condition of stability such that further heating and cooling through a range of 80° had but little permanent effect upon its conductivity, it still showed, when hard drawn, an appreciable negative coefficient. It was then annealed three times at red heat, specific resistance and coefficient being determined for the range of 20° to 100° after each annealing. The results were as follows:—

Condition.	Specific resistance.			Coefficient.
	20°.	100°.	20°.	
Rather hard..........	46·10	45·99	46·09	−0·000024
Once annealed........	45·10	45·18	45·09	+0·000021
Twice annealed.......	44·07	44·33	44·06	+0·000068
Thrice annealed......	42·76	43·58	42·74	+0·000192

A number of similar alloys showed, when hard rolled, a coefficient very near to zero, sometimes positive, sometimes negative. After annealing at 300° to 400°, a well-defined negative coefficient, after annealing at a red heat, a still larger positive coefficient, was produced. It was found that the positive coefficient produced by annealing could be reduced again by rolling the alloy.

The relation of composition to the temperature coefficients was determined. With 10 per cent. of ferro-manganese, the change of resistance is less than 1 per cent. for 100°. Alloys containing from 15 to 20 per cent. of ferro-manganese have exceedingly small coefficients, the coefficient at 18 per cent. being practically zero. As above shown, the coefficient may be made to undergo a considerable alteration by varying the temper of the metal. The marked influence of temper upon the conductivity of these alloys renders it difficult to determine the precise law of the change in specific resistance with the composition. It would, however, appear from the results that the resistance increases nearly in direct proportion to the percentage of ferro-manganese. H. C.

Conductivity of Distilled Water. By W. Ostwald (*Ann. Phys. Chem.* [2], **40**, 735—737).—The author contends, as against Pfeiffer, that the electrical conductivity of distilled water is in great measure due to the presence of carbonic anhydride in solution, which can only be removed by distillation over a considerable quantity of a base, by preference lime. J. W.

Behaviour of Mannitol towards Boric Acid. By G. Magnanini (*Zeit. physikal. Chem.*, **6**, 58—70).—It is well known that some action takes place between boric acid and mannitol when in solution, and the assumption has been made that the two combine to form ethereal salts. In order to test this view, the author has determined the conductivity of solutions of boric acid containing different amounts of mannitol. The apparatus used was that described by Ostwald (Abstr., 1889, 4), and the molecular conductivities μ'_v and μ''_v of boric acid and of mannitol were calculated on the assumption that in each case the conductivity was due solely to the presence of one of the two substances.

The molecular conductivity of boric acid is found to be enormously increased by the addition of mannitol, the increase being greater the larger the amount of mannitol added. One must therefore assume, since mannitol is a non-conductor, that some electrolyte is formed in the solutions, increasing in amount with the mannitol added. It further appears that the molecular conductivity of boric acid in the presence of mannitol decreases with rising dilution, a behaviour which is opposed to that of all other electrolytes. One may, however, assume in this case that the compound of boric acid and mannitol first formed is subject to hydrolysis, and therefore will be decomposed by the addition of water. The decomposition of the electrolyte with increasing dilution then explains the decrease in the conductivity which takes place. This view is further supported by the fact that solutions containing a large proportion of mannitol behave normally up to a certain dilution, the conductivity regularly increasing; but a maximum is after a time reached, and a decrease then sets in, no doubt due to the fact that the hydrolytic has become greater than the electrolytic dissociation.

Application of the Guldberg-Waage theory leads to the conclusion that a compound of boric acid and mannitol is formed in the above solutions, containing 3 molecules of the former to 1 molecule of the latter. The amount formed at constant temperature is a function of the amounts of water, boric acid, and mannitol, and may be determined with respect to the last two substances in accordance with the laws of chemical equilibrium, since the electrical conductivity of a solution containing different amounts of boric acid and mannitol in the same amount of water varies in accordance with the same laws.

Other substances containing hydroxyl groups are found to increase the conductivity of boric acid solution. Dulcitol was examined, but a simple relation was not found in this case. Measurements are also given for solutions of tartaric and boric acids, which lead to the conclusion that these form at least one compound with one another.

H. C.

Effects of the Silent Discharge. By P. SCHUTZENBERGER (*Compt. rend.*, **111**, 14—18; compare this vol., 691, 692, and 961).—The apparatus employed consisted of a vertical discharge tube, with armatures of acidulated water. The lower end of the tube was drawn out and connected, by means of a semi-capillary copper tube, with a horizontal glass tube 1·3 m. in length and 10 mm. in diameter, containing 0·3 m. of pumice and phosphoric anhydride, 0·25 m. of pumice and sulphuric acid, 0·25 m. of moist potash-pumice, and 0·25 m. of spongy platinum. The spongy platinum was kept at a dull red heat, in order to remove the last traces of oxygen from the combustible gases used in the experiments.

A current of gas was passed slowly through the apparatus, and was subjected to the action of the discharge. Under these conditions, the gas in the annular space through which the discharge passed was continually renewed, and the gaseous products were carried forward into the collecting apparatus, which contained phosphoric anhydride to absorb the water, and potash to absorb the carbonic anhydride.

A slow current of carbonic oxide was passed through the apparatus for six hours without any discharge; there was no alteration in the weight of the collecting apparatus. Four experiments were made with the discharge, from 0·2 to 0·3 gram of solid matter being condensed in each case. In three experiments this product was deep brownish-black, and in one it was pale-brown in colour. It was only very partially soluble in water, and the brownish-yellow solutions were very feebly acid. The proportion of hydrogen did not exceed 0·2 to 0·3 per cent., and the ratio of carbon and oxygen was $C_4 : O_3$ in one case, and $C_5 : O_4$ in another.

A soluble and acid product obtained by renewing the gas in the apparatus at the end of every three hours only had the composition C, 42·1; H, 1·4; O, 56·5 per cent.; whilst when the water and carbonic acid were absorbed every half hour, the results were as follows:—

C per cent.	H per cent.	O per cent.
47·28	0·48	52·24
45·02	0·60	54·38
45·00	0·59	54·41

The longer the action of the discharge on the same quantity of gas, the greater the proportion of hydrogen and oxygen in the condensed product. The solubility and acidity increase with the time of action, and the ratio between the carbonic anhydride formed and the condensed product diminishes up to a certain limit. In four experiments in which the gas was continually renewed, the ratio of the weight of the condensed product to the weight of the carbonic anhydride formed was 1·39, 1·38, 1·39, 1·35, whilst the continued action of the discharge on one and the same mass of gas gave a ratio of 2·2 after an hour, and 2·5 to 2 6 after four days. The ratio of the oxygen and hydrogen in the condensed product is not the same as in water; there is an excess of oxygen. From the composition of the condensed product and the weight of gaseous carbonic anhydride formed at the same time, it follows that only about half the oxygen required to produce the carbonic anhydride has been obtained from the condensed carbonic oxide, and hence oxygen must have been derived from external sources. Moreover, the oxygen introduced from without is more than could exist in combination with the hydrogen (also derived from external sources) in the form of water.

If a current of pure and dry nitrogen is passed through the apparatus, and is subjected to the action of the discharge, there is no alteration in the weight of the absorbing apparatus, and hence it follows that the elements of water do not pass through the glass in a combined condition, and, moreover, do not pass through cracks or pores in the glass. It would seem that the oxygen and hydrogen pass separately through the glass by a kind of electrolytic transportation, and are detected only when they come in contact in the annular space with some substance, such as acetylene, which can combine with the oxygen, or carbonic oxide, which combines with both oxygen and hydrogen. C. H. B.

Influence of a Magnetic Field on the Electrical Resistance of Gases. By A. WITZ (*Compt. rend.*, **111**, 264—266).—A magnetic field has no influence on the silent discharge in gases; its effect in the case of a Geissler tube must be attributed to the special construction of the tube, and the state of rarefaction of the gas which it contains. Such tubes seem to behave like condensers, and the effect of a magnet may be attributed to an alteration in their electrical capacity.

C. H. B.

Heats of Formation of Amides. By BERTHELOT and FOGH (*Compt. rend.*, **111**, 144—146).—The last column gives the heat of formation from the solid acid and the crystalline base with elimination of water.

	Molecular heat of combustion.		Heat of formation from elements.	Heat of dissolution at 14—14·5°.	
	Const. vol.	Const. press.			
Acetamide	288·0	288·1	72·9	−1·85	− 5·0
Propionamide..	435·6	436·0	88·4	−0·97	—
Benzamide	851·9	852·3	49·3	—	− 5·6
Succinimide ...	439·3	439·2	110·5	—	−23·1
Acetanilide	1016·1	1016·8	52·1	—	+13·9
Benzanilide ...	1582·2	1583 7	22·1	—	+ 7·1

The formation of the anilides develops more heat than the formation of the corresponding amides, a result which explains their greater stability in contact with water, the difference being increased because the heats of formation of the ammonium salts are greater than those of the aniline salts. C. H. B.

Heats of Formation of Sugars. By Berthelot and Matignon (*Compt. rend.*, **111**, 11—14).—

	Mol. wt.	Heat of combustion, 1 gram.	Molecular heat of combustion.		Heat of formation.
			Const. vol.	Const. press.	
Erythrol	122	4117·6	502·3	502·6	+219·6
Arabinose........	150	3714·0	557·1	557·1	+259·4
Xylose...........	150	3739·9	560·7	560·7	+235·8
Raffinose	504	4020·0	2026·1	—	+775·3
Inosite (racemic)..	180	3676·8	661·8	—	+318·0
Inosite (inactive)..	180	—	666·5	—	+313·3

The heat of formation of dextrogyrate and of lævogyrate inosite is 316·2 Cal., from which it follows that the inactive inosite contains a reserve of energy.

Heat of dissolution of erythrol at 24°, −5·54 Cal. Heat of dissolution of anhydrous raffinose at 18·1°, +8·38 Cal.; of hydrated raffinose at 17·7°, −9·72 Cal.

Differences between Heats of Formation.

Methyl alcohol (liquid) and glycol (liquid)........	+113 Cal.
Glyercol (crystallised) and erythrol (crystallised)	+114 „
Erythrol (crystallised) and mannitol (crystallised)	+113 × 2 Cal.

Ethyl alcohol and glycol	+41·5 Cal.
Propyl alcohol and glycerol	+42·7 × 2 Cal.
Butyl alcohol and erythrol	+43·5 × 3 „

From the last three numbers it will be seen that the heat of substitution of hydroxyl, OH, for hydrogen, H, increases in proportion to the hydricity of the alcohol. They also represent the difference between the heat of fixation of CH_2 (about 156 Cal.) and CHOH (about 113 Cal.). C. H. B.

Heats of Combustion of Sulphur Compounds. By BERTHELOT and MATIGNON (*Compt. rend.*, **111**, 9—11).—Determinations of the heats of combustion of carbon compounds containing sulphur have hitherto been somewhat unsatisfactory, owing to the difficulty of ensuring complete oxidation of the sulphur. If, however, the compound is burnt in a calorimetric bomb filled with oxygen under a pressure of 25 atmospheres, the oxidation of the sulphur is complete and instantaneous (compare this vol., p. 1462). If the compound contains very little hydrogen, the addition of camphor is necessary.

	Heat of combustion, 1 gram.	Molecular heat of combustion.		Heat of formation.
		Const. vol.	Const. press.	
Thiophen	7970·1	669·5	670·9	− 14·9
Taurine	3080·6	385·0	385·7	+ 185·7
Carbon bisulphide (liquid)	5217·0	396·4	398·1	− 22·6

Heat of formation of gaseous carbon bisulphide, −27·0 Cal.
C. H. B.

Stability of Salts alone and in presence of Water: Aniline Salts. By BERTHELOT (*Compt. rend.*, **111**, 135—144).—*Aniline Sulphate*:—Molecular heat of dissolution (284 grams) at 24°, −4·63 Cal.; heat of neutralisation of aniline by one equivalent of sulphuric acid, + 8 63 Cal. The heat of dissolution of aniline is given by the equation $Q = -(t - 11{\cdot}9)0{\cdot}0447$ Cal., and hence the neutralisation of one molecule of dissolved aniline by an equivalent of dilute sulphuric acid develops +9·21 Cal., a number 5·3 Cal. lower than the corresponding value for ammonia. The difference between the heats of formation of the two solid salts from dissolved base and acid is 4·3 Cal., and from gaseous constituents 5·1 Cal. The addition of an equivalent of sulphuric acid to a molecule of aniline sulphate absorbs −0 81 Cal., or, as in the case of sodium, potassium, and ammonium, the heat of formation of the acid sulphate is lower than that of the normal salt. An excess of aniline produces no sensible thermal disturbance, a fact which shows that combination between the base and the acid is very nearly, if not quite, complete. Nevertheless, aniline sulphate in solution undergoes slight dissociation, especially when heated, the extent of dissociation, although small, being distinctly greater than in the case of ammonium sulphate.

Thermochemical measurements show that sodium hydroxide completely displaces aniline from its sulphate even in presence of an excess of aniline. Ammonia also displaces the aniline, but in this case there is a slight division of the acid between the bases, a result due to the partial dissociation of the two sulphates in solution.

Aniline Nitrate and Chloride.—These salts stand in precisely the same relation to the corresponding ammonium salts as does aniline sulphate to ammonium sulphate. In the case of both bases, the heats of formation of the nitrate and chloride from the acid and base are the same.

Aniline acetate has not been isolated in the solid state. The addition of acetic acid to an equivalent quantity of aniline at 24° develops +1·53 Cal., and if it is assumed that the heat of fusion of the acetic acid is the same as that of aniline acetate, the heat of formation of this salt from gaseous constituents is +10·1 Cal. The heat of formation of the ammonium compound is + 8·4 Cal. greater, and hence the combination of aniline with acetic acid is much less complete than with the acids previously mentioned. A solution of aniline and acetic acid in equivalent proportions gives a further development of + 1·41 Cal. on addition of a second equivalent of acetic acid, and + 0·73 Cal. with a second equivalent of aniline. In solution, therefore:

NH_2Ph + HOAc .... develops +3·8 Cal.
NH_2Ph + 2HOAc .. " +5·2 "
$2NH_2Ph$ + HOAc .... " +4·8 "

Aniline Benzoate.—Aniline and benzoic acid, when gently heated together in equivalent proportions, yield a homogeneous liquid which crystallises on cooling and dissolves completely in water. If the solution is concentrated by evaporation, it deposits crystals of benzoic acid, and the dissociation of the salt is practically complete. The heat of dissolution of the crystalline product is −4·79 Cal., and from this and the heat developed by the action of sodium hydroxide it follows that the action of the liquid aniline on the solid acid develops + 2·7 Cal. The heat of formation of the benzoate from gaseous constituents would be + 11·3 Cal., and the difference, 5·7, between this number and the value for the ammonium salt is nearly the same as in the case of the nitrates. The formation of the solid salt from dissolved acid and base is + 9·8 Cal., or 5 Cal. higher than in the case of the acetate. It follows that though the salt partially dissociates on solution, the dissociation is much less than in the case of the acetate.

The crystalline product spoken of as aniline benzoate is really a mixture of crystals with an oily substance, and if the crystals are separated by repeated pressing between filter paper, they are found to have the composition of the acid benzoate, $PhNH_2,2C_7H_6O_2$.

C. H. B.

Equilibrium and Reciprocal Displacements between Volatile Organic Bases. By BERTHELOT (*Compt. rend.*, **111**, 289—296; compare preceding abstract).—*Piperidine* is alkaline to litmus, and when treated with water, heat is developed in gradually increasing quantity; $C_5H_{11}N + 1\frac{1}{8}H_2O$ develops +1·6 Cal.; + $3H_2O$, +2·3 Cal.; + $9H_2O$, +3·5 Cal.; + $300H_2O$, +6·46 Cal. These results indicate the formation of a partially dissociated hydrate, and in this respect piperidine resembles trimethylamine. The tertiary bases, in fact, show in a well marked degree that power to combine with the elements of water which characterises the quaternary bases. This fact has to be taken into account in determinations of the heats of neutralisation of these compounds.

$C_5H_{11}N$ diss. + HCl diss. develops +13·32 Cal.; $C_5H_{11}N$ liq. + HCl gas = $C_5H_{12}NCl$ solid, develops +38·2 Cal.; $C_5H_{11}N$ gas + HCl gas = $C_5H_{12}NCl$ solid, develops +46 Cal. These numbers are of the same order of magnitude as the corresponding numbers for the ammonium compounds.

$C_5H_{11}N$ diss. + $\frac{1}{2}H_2SO_4$ diss. develops +15·5 Cal.; $C_5H_{11}N$ diss. + H_2SO_4 diss. develops +14·3 Cal. As in the case of pyridine and the alkali metals, the heat of formation of the normal salt is greater than that of the hydrogen salt.

Both piperidine and ammonium salts are slightly dissociated in solution, and there is reciprocal displacement to a certain extent when the salts are mixed. $C_5H_{11}N$ diss. + NH_4Cl diss., develops +0·4 Cal. and $C_5H_{11}NHCl$ diss. + NH_3 diss. absorbs −0·45 Cal., the sum of the two differences being practically identical with the difference between the heats of neutralisation.

The author is unable to confirm Colson's statement (this vol., p. 1368) that piperidine displaces calcium from calcium chloride. On the contrary, the thermal disturbances show that sodium hydroxide and calcium hydroxide displace piperidine almost, if not quite, completely, from solutions of its hydrochloride, and freshly precipitated calcium hydroxide readily dissolves in strictly equivalent proportions in a solution of piperidine hydrochloride. If the piperidine has been exposed to the air and has absorbed carbonic anhydride, then it precipitates calcium salts, and if carbonic anhydride is passed into a solution of calcium chloride containing piperidine, calcium carbonate is precipitated.

On the other hand, if piperidine is poured into a saturated solution of calcium chloride, a precipitate forms immediately, and the whole liquid becomes solid. The precipitate is not calcium hydroxide, but re-dissolves completely on addition of water. Calcium nitrate and acetate behave similarly, but the precipitate with the chloride requires the greatest quantity of water to dissolve it, and in this case also the development of heat is greatest. It is probable that these precipitates are compounds of the chloride or oxychloride with piperidine, analogous to the ammoniacal compounds of calcium and other metals. Piperidine also precipates barium chloride, but only from a saturated solution, and without decomposing it, the piperidine exerting a dehydrating action similar to that of hydrochloric acid. Like ammonia, however, piperidine precipitates magnesium salts.

Pyridine.—The data are as follows:—

C_5H_5N liquid + $220H_2O$ at 22°	develops	+2·12	Cal.
C_5H_5N diss. + HCl diss..............	„	+5·1	„
C_5H_5N diss. + $\frac{1}{2}H_2SO_4$ diss..............	„	+7·1	„
C_5H_5N liq. + $\frac{1}{2}H_2SO_4$ diss..............	„	+9·22	„
$C_5H_5N.\frac{1}{2}H_2SO_4$ + $\frac{1}{2}H_2SO_4$..............	absorbs	+0·87	„

The first two values agree with Colson's determinations:—

C_5H_5N diss. + NH_4Cl diss...... develops 0·0 Cal.
C_5H_5N,HCl diss. + NH_3 diss.... „ +7·3 „

Ammonia displaces pyridine almost completely, but there is some evidence of a division of the acid, due to dissociation of the ammonium salt, as in the case of aniline.

The addition of pyridine to calcium chloride solution develops a small quantity of heat (0·12 Cal.), but there is no precipitate. If, however, carbonic anhydride is passed into the liquid, calcium carbonate is precipitated, a reaction which does not take place in the case of aniline.

In the case of piperidine and pyridine, there is some division of hydrochloric acid, but the greater part remains in combination with the first base.

Aniline.—The heats of formation of the salts of aniline are almost identical with those of the salts of pyridine, and when aniline is added to a solution of pyridine hydrochloride there is a partial displacement of the pyridine. Pyridine displaces aniline from its sulphate to a considerable extent, although not completely. In no case, in fact, is displacement by pyridine complete, the distribution of the acid being determined by the degree of dissociation of the two salts.

Boiling Points of Substances are a Function of their Chemical Nature. By M. Wildermann (*Ber.*, **23**, 1468—1470, and 2146—2151; compare this vol., p. 941).—The author quotes further instances in support of the law given in his previous paper with regard to the boiling points of substances. Objection is raised to the view recently put forward by Guldberg (this vol., p. 1043) that the ratio T/T_1, where T is the absolute boiling point and T_1 the absolute critical temperature, is practically constant; from which it also follows that the ratio T/T' of the two boiling points at the pressures *n* and *np* will be constant for substances the critical pressures of which do not greatly differ. It was shown by the author in the paper above quoted, that the relation of boiling point to pressure is a function of the chemical nature of a substance. The above ratio T/T' cannot therefore be the same function of the pressure for substances of different chemical nature, so that even if such substances have equal critical pressures, the values for the ratio T/T' will not be equal.

H. C.

Determination of the Vapour Pressures of Solutions. By G. Charpy (*Compt. rend.*, **111**, 102—103).—The solution is placed in a large test tube, the upper part of which contains a small condensation hygrometer. The space above the liquid is allowed to become saturated with the vapour of the solvent, the process being accelerated, if necessary, by reducing the pressure, and the dew point is determined. If the law of the variation of the vapour pressure of the solvent is known, the vapour pressure of the solution at the temperature of the experiment can be readily calculated. The accuracy of the determination is greater, the feebler the pressure that has to be measured. This method is applicable to the case of solutions which attack mercury, and which, therefore, could not be introduced into a barometric tube. C. H. B.

Some Vapour-density Determinations. By A. Krause and V. Meyer (*Zeit. physikal. Chem.*, 6, 5—9).—The method described by Demuth and Meyer (this vol., p. 440) for determining the vapour density of a substance below its boiling point is found to be still applicable when other gases such as air, nitrogen, or even carbonic anhydride are used in place of hydrogen to fill the vaporising bulb of the apparatus. The vaporisation is then much slower, but determinations of the vapour densities of xylene at 40°, and of paranitrotoluene at 33°, below their boiling points, in air and in carbonic anhydride, show that perfectly accurate results are obtained. The above gases may therefore be employed in cases where hydrogen cannot be used, but it is preferable to use the latter in all cases where possible.

Using the Dumas method, Cahours found that the theoretical vapour density of acetic acid is first reached at 250°. The authors find that by their method the theoretical vapour density can be reached at about 160°. The results obtained were as follows:—

Temp.	Krause and Meyer.		Cahours.	Temp.	Krause and Meyer.		Cahours.
100°	2·67	2·60	—	160°	2·12	2·18	2·48
125	2·51	2·42	3·20	190	2·14	2·07	2·30
140	2·28	2·26	2·90	—	—	—	—

The theoretical number is 2·08.

Iodine, according to Troost, at the temperature of boiling sulphur, already shows dissociation when under a reduced pressure. No sign of dissociation was, however, found by the authors when iodine was allowed to vaporise at the above temperature in the presence of a large excess of air. An experiment performed with sulphur at the same temperature, and in an atmosphere of nitrogen, gave a vapour density corresponding with S_7. This is looked upon as accidental, as the vapour density is not constant at these temperatures. H. C.

Osmotic Experiment. By W. Nernst (*Zeit. physikal. Chem.*, 6, 37—40).—If we have two solutions in the same solvent of different concentrations, separated by a layer of a second liquid in which the solvent is soluble, but not the dissolved substance, the liquid will act as a semi-permeable material, allowing the passage of the solvent from the solution of less to that of greater concentration, but not allowing the passage of the dissolved substance. This is shown to be the case with solutions of benzene in ether separated from one another by a membrane saturated with water. H. C.

Rôle of Solid Substances in Chemical Equilibrium. By A. Horstmann (*Zeit. physikal. Chem.*, 6, 1—4).—It is a matter of common experience that the relative amount of a solid substance exercises no influence on chemical equilibrium, or, as it is usually expressed, the active mass of a solid substance appears to be constant. Thus when carbonic anhydride is in contact with a mixture of calcium carbonate and lime, although seemingly the mixture should absorb a greater quantity of carbonic anhydride, the greater the amount of lime present, this is not found to be the case, the tension of the gas being independent of the proportion of the two solids in the mixture. This fact has not hitherto been satisfactorily explained, but Van't Hoff's recent views with regard to the existence of solid solutions (this vol., p. 1044) now open out a way for such an explanation.

Two solid substances, A and B, will, as a rule, form with one another two saturated solutions, the one containing a small quantity of B in a large quantity of A, and the other a small quantity of A in a large quantity of B. Under these circumstances, equilibrium will, within very wide limits, be independent of the proportion of the two solids. In the case of calcium carbonate just considered, one may assume that there are two solutions, one containing aCaO in $100CaCO_3$, and the other $b$$CaCO_3$ in 100CaO, where a and b are both small quantities. According to a well known thermodynamic principle, the tension of carbonic anhydride above these two solutions must be the same, and this will remain constant as long as the two solid solutions are present at the same time, whatever be the relative amounts of the solid substances; for the addition or removal of carbonic anhydride can only alter the amounts of the two solutions, but not their composition, and hence the tension also remains unaltered. The tension will only become variable when the quantity of one of the constituents is so small that only one of the two solutions can be formed. H. C.

Affinity Coefficients of Alkyl Halogen Compounds and of Amines. By N. Menschutkin (*Zeit. physikal. Chem.*, 6, 41—57).—In a former paper (Abstr., 1888, 901), the author has shown that the nature of the solvent exercises a very material influence on the velocity of the chemical reaction there studied. In order to submit this influence to a further examination, the velocity of the action of triethylamine on ethyl iodide in various neutral and chemically indifferent solvents was determined. The following table gives the comparative values of the velocities in different solvents, that in benzyl alcohol being taken as 100 (the greatest velocity):—

	Hydrocarbons.		
Hexane	0·13	Xylene	2·2
Heptane	0·17	Benzene	4·4
	Halogen Compounds.		
Propyl chloride	4·0	Bromobenzene	20·3
Chlorobenzene	17·4	α-Bromonaphthalene	84·9
	Ethers.		
Ethyl isoamyl ether	0·47	Phenetoïl	16·0
Ethyl ether	0·57	Anisoïl	30·3

Ethereal Salts.

Isobutyl acetate	4·3	Ethyl benzoate	19·4
Ethyl acetate	16·7		

Alcohols.

Isobutyl alcohol	19·4	Allyl alcohol	32·5
Ethyl alcohol	27·5	Methyl alcohol	38·0

Ketones.

Acetone	45·7	Acetophenone	97·3
Acetone (14·5 vol). Water (0·5 vol.)	66·9		

The velocity is least for the hydrocarbons and ethers; then come the ethereal salts and alcohols, and lastly the ketones, for which the velocity is greatest. Comparing members of the same homologous series, it is evident that the velocity is most retarded by compounds of highest molecular weight. Unsaturated compounds appear to assist the reaction, and this is especially noteworthy in the case of aromatic compounds. The velocities for the haloïd compounds are greater than those for the hydrocarbons, and bromine gives higher values than chlorine.

The velocity of the action of propyl iodide on triethylamine in different solvents was also studied. The numbers obtained are smaller than those for ethyl iodide, but a very similar relation is observed among them. The peculiar influence of the solvents in these cases justifies the conclusion that solutions in organic solvents are not mere mixtures, but that a distinct specific attraction exists between the solvent and dissolved substance. H. C.

Distribution of Hydrogen Sulphide between the Metals of two Dissolved Salts. By G. Chesneau (*Compt. rend.*, **111**, 269—271).—Hydrogen sulphide was added to a solution containing lead nitrate and copper nitrate in equal molecular proportions. Direct experiments showed that in the case of both salts incomplete or exact precipitation yields always a monosulphide. The division of the hydrogen sulphide between the two metals takes place in the direction indicated by the thermochemical data. Copper is precipitated more rapidly than lead, and the composition of the precipitate varies continuously with the proportion of hydrogen sulphide. The ratio of copper to lead also varies with the time during which the three compounds remain in contact; it first decreases, attains a minimum after a few minutes, and then gradually increases. C. H. B.

Berthollet's Laws. By A. Colson (*Compt. rend.*, **111**, 103—106).—Pyridine, aniline, and nicotine give no precipitate with solutions of calcium salts, and hence are exceptions to one of the laws of Berthollet. The heat of neutralisation of diisobutylamine is practically the same as that of calcium hydroxide, and, like the latter, the amine precipitates magnesium hydroxide, but is expelled from its salts by potassium hydroxide. Now if double decomposition depends on affinity, and not on the nature of the base, the salts of diisobutylamine should not be decomposed by pyridine, aniline, or nicotine, and the author found that the sulphate and chloride are not decomposed, after first proving that the solubility of the amine in water is not affected by the presence of the other bases mentioned.

Organic and inorganic bases may be divided into two groups, the one being comparable to the alkalis, and the other to feebler metallic bases, the ratio established for one acid holding good as a general rule for all the others. When an alkaline base and a feeble base are simultaneously in presence of the same acid, the affinity of the alkaline base alone seems to be active, and the salts of the strong base are not decomposed by the feeble base, whatever be the nature and solubility of the bases, provided that they form soluble salts. In other words, Berthollet's laws do not hold good. From a thermochemical point of view, this fact may be stated approximately in the following terms: When two bases, by their separate union with the same acid, develop *very different* quantities of heat, the salts formed with the greater development of heat are not decomposed by the feebler base, whatever may be the direction of the interaction indicated by Berthollet's laws. C. H. B.

Reactions of Organic Bases. By A. Colson (*Compt. rend.*, **111**, 266—268).—Piperidine precipitates calcium from solutions of its soluble salts, although the heat of formation of piperidine chloride, +13 Cal., is less than that of calcium chloride, +14 Cal. Moreover, the heat of formation of piperidine chloride in any state is less than that of ammonium chloride, and yet ammonia does not precipitate solutions of calcium chloride.

Pyridine displaces aniline from solutions of its chloride, although the heat of formation of aniline chloride is greater than that of pyridine chloride. The result cannot be attributed to the formation of a pyridine dihydrochloride, for the latter is unstable in presence of water, and its heat of formation is very small.

It would seem that in these cases Berthollet's laws hold good, but the ordinary thermochemical laws do not, and the author concludes that for bases of the same order, Berthollet's laws are true, whatever the direction of change indicated by the thermochemical data.

C. H. B.

New Principle of Determining Molecular Weights. By W. Nernst (*Zeit. physikal. Chem.*, 6, 16—36).—It has been shown by Van't Hoff and Tammann that iso-osmotic solutions have equal vapour tensions. Regarding the process of dissolution as equivalent to that of vaporisation (Nernst, this vol., p. 3), the tensions of different solutions towards any particular solvent will be subject to the same law. Hence if two iso-osmotic aqueous solutions are shaken, say, with carbon bisulphide, the latter will remove equal quantities of water from each. If the osmotic pressures of the solutions differ, that of lower osmotic pressure will part with more water than that with the higher. But since the osmotic pressure of a solution changes with the amount and the nature of the dissolved salt which it contains, the amount of water or other solvent which passes from the solution into the carbon bisulphide or other liquid will vary as the dissolved salt varies. The osmotic pressure being also dependent on the molecular weight of the dissolved substance, there will obviously be a relation between this latter and the amount of solvent which will be dissolved out of the solution by some second liquid. This relation can be determined from thermodynamical considerations, and may be formulated as follows: The relative decrease in solubility towards some second liquid which a solvent undergoes, owing to the addition of some foreign substance, is as the number of molecules of the dissolved foreign substance to the number of molecules of the solvent. Hence if n is the number of foreign molecules dissolved in 100 mols. of the solvent, and a and a' the solubilities of the pure solvent and of the solution, $(a - a')/a' = n/100$. This law was tested and found to be correct for solutions of various substances in valeric acid and ether, the second liquid used in each case being water. The amount of valeric acid dissolved out by the water was determined in each case by titration, and the amount of ether by taking the specific gravities of the aqueous solutions. If x is the number of grams of a substance of molecular weight M dissolved in 100 gram mols. of the solvent, $n = M/x$, and we thus have a method of determining the molecular weight of the dissolved substance by measuring the solubility of its solution in some second solvent.

If a mixture of two liquids, such as ether and water, is cooled to a sufficiently low temperature, one of them, in this case the water, will begin to freeze. The point at which this will take place will be that corresponding to the reduction in the freezing point of water caused by the addition of the ether. If in the ether a third substance is dissolved which is not soluble in water, then, in accordance with the law stated above, the solubility of the ether in the water will be lessened, and hence the freezing point of the aqueous solution will rise If t_0 is the freezing point of a solution of pure ether in water, and t the freezing point after the addition of a foreign substance of molecular weight M, m grams of the latter being dissolved in 100 grams of ether, then $t/(t_0 - t) = 74m/100M$. The method can, therefore, be used to determine an unknown molecular weight, and experiments are quoted which demonstrate its correctness. Solutions other than those of ether and water may, of course, be used, if they fulfil the above necessary conditions. H. C.

Inorganic Chemistry.

Carbon an Impurity in Hydrogen affecting Determinations of its Atomic Weight. By E. W. Morley (*Amer. Chem. J.*, 12, 460—463).—All commercial varieties of zinc, including the purest zinc obtainable from the manufacturers of pure chemicals, when dissolved in dilute acids, give hydrogen containing carbon compounds, which are converted into carbonic anhydride on passing the gas over hot copper oxide. The hydrogen obtained by the electrolysis of an alkaline hydroxide is likewise contaminated, unless care is taken to remove the carbonate present by precipitation with barium hydroxide. The bearing of these facts on the determination of the atomic weight of hydrogen is obvious, since hydrogen containing carbon compounds will have too high a specific gravity; and when weighed and burned, and the resulting water weighed, the atomic weight of hydrogen will appear to be too large.

The only known satisfactory method of obtaining pure hydrogen for atomic weight determinations is by the electrolysis of dilute sulphuric acid. The author, by this method, has succeeded in obtaining hydrogen, at the rate of from 10 to 20 litres per hour, in which there is no carbon, no sulphur; in which there is presumably no oxygen, and, finally, in which the resulting nitrogen is too small to be detected by a process which shows the presence of one-hundredth of a c.c. of nitrogen in a litre of hydrogen. G. T. M.

Atomic Weight of Oxygen. By W. A. Noyes (*Amer. Chem. J.*, 12, 441—460; compare Abstr., 1888, 411, 647, and 649).—In a previous paper (Abstr., 1889, 672), the author expressed the opinion that some undiscovered source of constant error existed both in his and in Cooke's determinations of the atomic weight of oxygen. Further experiments, however, now show that such cannot be the case, and that the atomic weight lies very close to, and is probably very slightly less than, the value 15·896 (mean of 24 determinations). The apparatus used was the same in principle as that employed in his previous experiments (*loc. cit.*); the hydrogen was obtained by the electrolysis of a solution containing 15—20 per cent. of sulphuric acid, and every precaution was taken to remove impurities from it, and to prevent leakage in the apparatus. The author has shown that these two objects were attained.

Experiments made with the desire of substituting lead chromate, manganese dioxide, or litharge for the copper oxide gave unsatisfactory results; although, in the case of manganese dioxide, one determination, after necessary corrections for retained water had been allowed, gave the value 15·904. This result may be regarded as confirmatory of those obtained when the author employed copper oxide. G. T. M.

Density of Nitrogen and Oxygen according to Regnault, and the Composition of the Air according to Dumas and Boussingault. By A. Leduc (*Compt. rend.*, 111, 262—264).—If the composition of the air by weight is calculated from the known composition by volume and the densities of oxygen and nitrogen as given by Regnault. the numbers obtained are, oxygen 23·58, nitrogen 76·42. According to Dumas and Boussingault the numbers are, oxygen 23·0 (22·9—23·1) and nitrogen 77·0. The author considers that this difference is most probably due to small errors in Regnault's numbers, namely, 1·10563 for oxygen and 0·97137 for nitrogen. Dumas found oxygen = 1·1057 and nitrogen = 0·972. Some preliminary determinations of the density of nitrogen by the author gave values between 0·972 and 0·973. C. H. B.

Rhombic Sulphur from Hydrogen Sulphide. By F. B. AHRENS (*Ber.*, **23**, 2708).—When pyridine or picoline is saturated with hydrogen sulphide and allowed to remain in open or loosely closed vessels, sulphur gradually separates out in small, lustrous crystals, consisting of rhombic octahedra. Those from picoline are larger, but less sharply developed than those from pyridine. It is probable that hydrogen sulphide first unites with the base forming an unstable additive compound, which is gradually decomposed by the oxygen of the air with separation of sulphur; the latter first remains dissolved in the base, but soon separates out in the crystalline form This view is confirmed by the fact that the pyridine bases always contain water after the sulphur has separated

H. G. C.

Action of Sulphurous Anhydride on Metals. By J. UHL (*Ber.*, **23**, 2151—2154).—Pure palladium foil decomposes pure dry sulphurous anhydride at a moderately high temperature in accordance with the equation—$Pd + 3SO_2 = PdS + 2SO_3$. The action ceases, however, after a short time owing, probably, to the fact that the metal becomes coated with sulphide. Platinum behaves like palladium under the same conditions, but gold decomposes the gas into sulphuric anhydride and sulphur.

When copper is heated in a stream of sulphurous anhydride, it is converted into cuprous sulphate and cuprous sulphide, a small quantity of a colourless sublimate being also formed; if the product is treated with water to dissolve the sulphate, and the dried residue containing copper sulphide is heated in a stream of hydrogen, evolution of hydrogen sulphide takes place. It was also found that freshly prepared, well dried copper sulphide is decomposed by hydrogen at a dull red heat with evolution of hydrogen sulphide; after about 15 minutes, the presence of metallic copper can be observed, and, on further heating, a considerable quantity of the sulphide is reduced. This fact proves that the method at present employed for the estimation of copper, namely ignition of the sulphide in a stream of hydrogen, cannot yield accurate results.

When silver is heated in a stream of sulphurous anhydride, it is converted into sulphate and sulphide, a very small quantity of sulphuric anhydride being also formed. Cadmium, under the same conditions, is converted into the sulphate and sulphide; the sulphide is not decomposed on ignition in a stream of hydrogen.

Mercury and bismuth are not acted on by sulphurous anhydride at a moderately high temperature, but magnesium glows vividly in the gas, even when only gently heated, yielding the sulphate, sulphite, and sulphide. Antimony is converted into the orange trisulphide and trioxide on ignition in sulphurous anhydride; aluminium, zinc, nickel, and cobalt seem to be partially converted into the sulphides.

F. S. K.

Expansion of Silica. By H. LE CHATELIER (*Compt. rend.*, **111**, 123—126).—The following results were obtained with (1) a brick of tridymite obtained by treating a brick of quartz at 1600°, (2) chalcedony heated at 1500°; sp. gr. 2·16, (3) calcined quartz. The numbers represent the elongation in mm. per 100 mm.:—

	15°.	95°.	130°.	170°.	245°.	270°.	360°.	480°.	570°.	590°.
(1.)	0·0	0·16	0·22	0·42	0·62	—	—	0·95	—	1·02
(2.)	0·0	0·06	—	0·20	1·23	—	1·29	—	—	—
(3.)	0·0	—	—	—	—	0·20	—	—	0·35	—

	600°.	650°.	700°.	900°.	990°.	1050°.
(1.)	—	—	1·09	1·07	—	1·05
(2.)	—	1·40	—	—	—	1·53
(3.)	0·41	—	—	—	0·45	—

Between 130° and 170°, the tridymite suddenly expands, the elongation being about 0·15 per cent., and this seems to correspond with the point of transformation, 130°, observed by Mallard. Tridymite shows a maximum expansion at about 750°, a phenomenon which has not previously been observed for any other substance. Between 170° and 245°, calcined chalcedony also shows a sudden elongation of 1 per cent., the exact temperature at which this takes place being 210°. It would follow from this transformation that this variety of silica cannot be regarded as amorphous. Calcined quartz expands continuously as the temperature rises, but the value of the elongation at 1000° is much lower than for any other variety of silica, and is intermediate between that of porcelain and that of glass; it follows therefore that when heated to a high temperature in presence of a small quantity of bases and suddenly cooled, quartz is really converted into amorphous silica. C. H. B.

Reduction of Oxygen Compounds by Magnesium. By C. Winkler (*Ber.*, 23, 2642—2668; see also this vol., pp. 331, 451, 693).—When a spiral of magnesium ribbon is ignited and plunged into carbonic anhydride, it continues to burn brightly, although in a somewhat altered manner, a slight, crackling noise being heard, whilst the burning particles of magnesium are projected against the sides of the vessel. The magnesia is coloured more or less grey from the presence of a little carbon, which is, however, only formed in very small quantity, carbon monoxide being the chief product. It is probable that the heat evolved by the burning magnesium dissociates the carbonic anhydride into carbon monoxide and oxygen, the latter then uniting with the magnesium vapour with explosive violence, and causing the above-mentioned scattering of the burning particles.

If a compact mass of magnesium ribbon be gently heated in a glass tube, and carbonic anhydride passed over it, the surface becomes rough, and covered with a greyish-black mixture of carbon and magnesium carbide, and carbon monoxide is found in the gas. At a full red heat, the magnesium ribbon bursts into flame, burning with an intense light, and forming a mixture of magnesia and charcoal. Magnesium wire under the same conditions does not ignite, but becomes coated with magnesium carbide; magnesium powder, on the other hand, causes formation of carbon monoxide below a red heat, and complete decomposition at a low red heat.

That magnesium can also cause the reduction of alkaline carbonates has been shown by Phipson (*Chem. News*, 9, 219), and by the author (this vol., p. 331). In the instances already investigated, the metal formed is volatile, and it was, therefore, interesting to see whether the carbonates of the alkaline earths exhibit a similar behaviour. It was found that when 1 mol. of calcium carbonate was heated with 3 atoms of magnesium in powder, complete reduction took place at a red heat, with incandescence. The product on treatment with hot water and acids gave off hydrogen contaminated with other unpleasant smelling gases. If only 2 atoms of magnesium are employed, the products are quicklime, charcoal, and magnesia, whilst 1 atom of magnesium gives quicklime, carbon monoxide, and magnesia. The carbonates of strontium and barium behave in a similar manner, except that the reaction is much more violent. An attempt was made to obtain the carbon formed in the last reaction in a crystalline condition by fusing the product with an excess of aluminium. The dark-coloured metallic mass, however, on treatment with acids, left a black residue consisting of amorphous carbon and small crystals of barium aluminate.

Burning magnesium ribbon or wire is at once extinguished when plunged into carbon monoxide. If the gas be passed over the same form of magnesium at a red heat, it only becomes coated with magnesium carbide. The powder, however, burns at a red heat with a dull glow, forming a black, friable product, consisting apparently of a mixture of magnesia and charcoal. On treatment with acids, this leaves a sooty powder, which, however, in this, as in all the above cases, contains considerable quantities of magnesium. That the latter is chemically combined is shown by the fact that it is not attacked by concentrated hydrochloric acid. On ignition, it is slowly converted into magnesia, and quantitative measurements of the amount of the latter led to the impossible formula MgC_{10}. It is, therefore, probably a mixture of magnesium carbide and charcoal, and, moreover always contains impurities derived from the vessel in which the reduction is carried out. Attempts were made to obtain a definite compound Mg_2C by heating the two substances in the required proportions in a current of hydrogen, and by heating 1 mol. of calcium carbonate with 5 atoms of magnesium. In both cases, however, only a partial reaction takes place; the product undoubtedly contains magnesium carbide, and gives off unpleasant smelling gases on treatment with acids.

The researches of Wöhler (*Annalen*, 107, 137, 369), Geuther (*J. pr. Chem.*, 95, 424), Phipson (*Proc. Roy. Soc.*, 13, 217), and Parkinson (this Journ., 1867, 128) have shown the strong tendency of silicon to unite with magnesium, and it was, therefore, thought advisable to investigate the compounds thus formed before examining the action of magnesium on silica. Wöhler obtained a compound to which he gave the formula Mg_4Si_3, whilst Geuther obtained a similar compound of the composition Mg_5Si_3. The author heated together magnesium and silicon in a current of hydrogen in the proportions required by the latter formula, and also in the proportion required by the formula Mg_2Si. Both products were very similar, the former having a slightly reddish tinge, whilst the latter is coloured pure greyish-blue. Both readily lose magnesium on ignition, and the author believes that the true compound is Mg_2Si, and that the other compounds obtained are formed from it by loss of magnesium. Both compounds evolve spontaneously inflammable hydrogen silicide with hydrochloric acid of sp. gr. 1·190, but if dilute acid be employed, the gas is not as a rule spontaneously inflammable. A portion of the silicon passes at the same time into Geuther's hydrated silicon oxide, $Si_3H_2O_5$, and possibly also into silicoformic anhydride, $Si_2H_2O_3$, and silicone, $Si_4H_4O_3$. Dilute sulphuric acid behaves in a manner similar to dilute hydrochloric acid, but the concentrated acid is reduced to sulphurous acid and sulphur. With hydrofluoric acid, it yields hydrogen only, and is not completely dissolved, as it becomes coated with insoluble magnesium fluoride. It is not attacked by aqueous potash, but is readily decomposed by a solution of ammonium chloride, according to the equation: $2Mg_2Si + 8NH_4Cl + 3H_2O = 4MgCl_2 + Si_2H_2O_3 + 8NH_3 + 6H_2$. Magnesium silicide also decomposes the salts of many heavy metals, with precipitation of the metal, and even with neutral solutions of alkaline chlorides it yields hydrogen on boiling, the solution becoming alkaline. The formation of hydrogen must be secondary, and due to the previous formation of the alkali metal.

The action of magnesium powder on silica has been recently investigated by Gattermann (Abstr., 1889, 342). The author in his experiments employed very finely ground quartz. When mixed with 2 atoms of magnesium powder, the reaction is extremely violent, even when only small quantities are employed, and the product is never homogeneous, showing in some places the blue magnesium silicide, and in others the brown silicon. If to the mixture an equal weight of magnesia be added before heating, the reaction proceeds quite quietly. The product obtained without magnesia, when powdered and again heated in hydrogen, assumes a pure brown colour, and scarcely evolves any hydrogen silicide with hydrochloric acid, whence it appears that not only magnesium, but also magnesium silicide, can reduce silica to silicon. If, therefore, 1 mol. of silica be heated with 1 atom of magnesium, silicon alone is formed, the reaction proceeding much more quietly. From this it would also appear probable that a silicon monoxide SiO does not exist. Powdered silicates are also reduced at a red heat by magnesium powder in the same manner as silica itself.

When titanium dioxide (1 mol.) is heated with magnesium powder (2 atoms) at a red heat in a current of hydrogen, reduction takes place with incandescence. The product must be allowed to cool in an atmosphere of hydrogen, as otherwise it readily catches fire in the air. After remaining for a night under glacial acetic acid, it is partially dried at a moderate heat, and then completely in a current of hydrogen at 150°. A brown powder is thus obtained, which contains no metallic titanium, but a lower oxide of the metal, mixed with magnesium in the form of magnesium titanate. From the quantity of oxygen taken up on heating the reduction product, it appears probable that the reaction takes place according to the equation $2TiO_2 + Mg = TiO + MgTiO_3$. If, however, the quantity of magnesium be decreased, products are obtained having the colours of the other lower oxides of titanium.

All attempts to prepare a compound of magnesium and titanium have been without success. A compound of titanium, hydrogen, and oxygen has, however, been obtained in the following manner. Titanium dioxide (1 mol.) was heated with magnesium powder (4 atoms) in a current of hydrogen. After cooling in the hydrogen atmosphere, the product was covered with water in a flask, and hydrochloric acid passed in drop by drop, until present in excess, almost pure hydrogen being evolved. The compound in suspension is collected, washed with hydrochloric acid, alcohol, and ether, and dried over sulphuric acid in a vacuum. It forms a black powder, which is not attacked by acids, and evolves hydrogen on treatment with aqueous potash, but remains unchanged in appearance. When heated by itself, it also gives off hydrogen without change of appearance, and on ignition in air forms titanic anhydride; the compound, however, still contains magnesium, probably as magnesium titanate. If in the numbers obtained on analysis the correction be made for a quantity of the latter compound corresponding with the magnesium found, the composition of the remainder is found to be Ti_3HO_4. The decomposition by heat would then be represented by the equation $Ti_3HO_4 = Ti_3O_4 + H$.

By the action of magnesium (2 atoms) on zirconium dioxide (1 mol.) at a red heat in a current of hydrogen, a black product was obtained which readily takes fire in the air, and which, after separating from unaltered magnesium, appears to have the composition ZrO, complete reduction to the metal not taking place. Zirconium monoxide may also be obtained by heating zirconium dioxide (1 mol.) and magnesium (1 atom). It is a deep-black powder, which readily undergoes oxidation forming titanium dioxide.

When zirconium dioxide and magnesium are heated in the proportion of 1 mol. of the former to 4 atoms of the latter, and the product treated just as described above under titanium, a black compound is obtained, which, like the titanium compound, is unacted on by acids, but evolves hydrogen on treatment with aqueous potash. On heating it, the flame of burning hydrogen is first seen, and then incandescence takes place, the dioxide being formed. From the analysis, it appears that, on the assumption that the magnesium found is present as zirconate, the new compound has the formula $Zr_3H_3O_4$. On heating by itself, it also evolves hydrogen, the reaction being possibly as follows:—$Zr_3H_3O_4 = 3ZrO + H_2O + H$.

The hydrogen evolved when the reduction product is treated with hydrochloric acid contains a small quantity of an impurity, which, from its general behaviour and peculiar odour, is probably hydrogen zirconide. H. G. C.

Beryllium. By G. Krüss and H. Moraht (*Ber.*, **23**, 2552—2556).—The authors have redetermined the atomic weight of beryllium. Beryllium oxide, purified as previously described (this vol., p. 697), was converted into the sulphate, $BeSO_4 + 4H_2O$, and weighed quantities of this salt, most carefully purified by recrystallisation, were reconverted into the oxide by ignition. The average of 14 determinations gave 4·514 as the equivalent, or 9·028 as the atomic weight of beryllium (O = 15·96); when O = 16, the atomic weight is 9·05, an even smaller value than that found by Awdejew. These results show that the impurity to which the yellowish-green colour of concentrated acid solutions of beryllium chloride is due (*loc. cit.*) has caused the results of previous atomic weight determinations to come out too high; the nature of this impurity is being investigated.

F. S. K.

Action of Metallic Cadmium on the Halogen Cadmium Salts: Cadmium Sub-hydroxide and Sub-oxide. By H. N. Morse and H. C. Jones (*Amer. Chem. J.*, **12**, 488—493).—When anhydrous cadmium chloride, contained in a long-necked flask of hard glass, is heated to the fusing point in a vacuum or in an atmosphere of nitrogen with an excess of metallic cadmium, the molten salt quickly assumes a fine garnet-red colour, which is not intensified by further heating. On cooling, the solidified mass has a greyish-white colour and a cleavage resembling that of talc or brucite; under the microscope, it appears homogeneous and free from metal; on analysis, it gives numbers which very closely approximate to those required by the formula Cd_4Cl_7. The new substance is a powerful reducing agent, and on heating fuses to a red liquid, which breaks up into metal and cadmium chloride; it is, perhaps, not a definite chemical compound, but a solution of cadmous chloride in cadmic chloride; and this view is supported by its behaviour towards water.

Anhydrous cadmium bromide, on similar treatment, behaves like the chloride, and gives a substance of the formula Cd_4Br_7; cadmium iodide appears to give a compound $Cd_{12}I_{23}$ (= CdI + $11CdI_2$). The properties of both these substances closely resemble those of the above described chloride, and all three compounds, when treated with water, yield the ordinary halogen salts of cadmium which dissolve; a small quantity of hydroxide, which renders the water turbid; and heavy, transparent, highly-lustrous, crystalline substances, which rapidly lose their crystalline appearance, and change to a white, amorphous powder, which is cadmous hydroxide.

Cadmous hydroxide, CdOH, is a strong reducing agent. It dissolves in dilute acids, yielding with nitric acid, oxides of nitrogen; with other acids, free hydrogen. When gently heated, it loses water, and forms a heavy, yellow powder, which, under the microscope, is found to consist of small, translucent crystals, and on analysis gives numbers corresponding with the formula Cd_2O. *Cadmous oxide*, on further heating, breaks up into a mixture of the normal oxide and the metal, the mixture having a distinctly green colour. G. T. M.

Crystallised Basic Cupric Nitrate. By G. Rousseau (*Compt. rend.*, **111**, 38—40).—The trihydrate $Cu2NO_3 + 3H_2O$ was heated with fragments of marble in sealed tubes at temperatures varying between 180° and 330° for a time varying from 24 to 48 hours. Small, thin, bluish-green tables crystallised out, identical with the rhombic plates obtained by Bourgeois (this vol., p. 714). With the hexahydrate $Cu2NO_3 + 6H_2O$, magnificent, transparent, green prisms, as much as 5 cm. long, were obtained. They are monoclinic, and are identical with the crystals which Wells and Penfield described, but which Bourgeois was unable to obtain by their method (*loc. cit.*). Under all conditions, and with either hydrate, the crystallised basic nitrate has the composition ascribed to it by Gerhardt, $3CuO,Cu2NO_3,H_2O$, and hence it would seem that the basic nitrate of Berthelot and Graham, $3CuO,N_2O_5,H_2O$, does not exist.

C. H. B.

Mercuricobaltammonium Salts. By G. VORTMANN and E. BORSBACH (*Ber.*, **23**, 2803—2806; compare this vol, p. 13).—On adding a strongly alkaline solution of potassio-mercuric iodide (Nessler's reagent) to luteocobalt chloride, the compound $Co_2N_{12}H_{32}(Hg{\cdot}OH)_4I_4(OH)_2$, is obtained as a voluminous, flocculent, light brown precipitate, insoluble in water, but sparingly so in acids. A red, crystalline powder with the formula $Co_2N_{12}H_{33}(HgI)_3I_6$ is formed on adding mercuric iodide solution (4 mols.) and sodium hydroxide (4 mols.) to luteocobalt chloride (1 mol.). On treating this compound with sodium hydroxide, the luteo-salt dissolves, and the bright red residue consists of $Co_2N_{12}H_{32}(HgI)_4I_6$; the same substance is also formed by the action of a large excess of sodium hydroxide on a mixture of luteocobalt chloride and mercuric iodide.

$Co_2N_{10}H_{20}(HgI)_4(Hg{\cdot}OH)_6I_6$ is obtained as a yellow precipitate on adding a little sodium hydroxide solution to a mixture of purpureocobalt chloride and potassio-mercuric iodide; it is sparingly soluble in acids, more readily in potassium iodide, and is also formed on digesting the double salt of purpureocobalt chloride and potassio-mercuric iodide with sodium hydroxide.

On adding 1—2 c.c. of a 10 per cent. solution of sodium hydroxide to roseocobaltdecamine chloride (1 gram), and potassio-mercuric iodide, a salt with the formula $Co_2N_{10}H_{27}(HgI)_3I_6$ is formed. With about 5 c.c. of the above solution of sodium hydroxide, the compound $Co_3N_{10}H_{26}(HgI)_4I_6$ is precipitated; whilst with a large excess of sodium hydroxide, a substance with the formula

$$Co_2N_{10}H_{26}(HgI)_4I_4(OH)_2$$

is obtained as a yellowish-brown powder.

$Co_2N_8H_{18}(HgOH)_6I_6$ is the only compound which could be obtained from purpureocobaltoctamine chloride.

On treating roseocobaltoctamine chloride with potassio-mercuric iodide and an equal amount of sodium hydroxide (10 per cent. solution), a brown precipitate of $Co_2N_8H_{21}(HgI)_3I_6$ is formed, soluble in nitric acid or hydrochloric acid. With 1·5—2 parts of sodium hydroxide, $Co_2N_8H_{20}(HgI)_4I_6$ is obtained; its colour is reddish-brown. A brown compound with the formula $Co_2N_8H_{20}(HgI)_4I_4(OH)_2$, is formed by the action of a large excess of sodium hydroxide.

J. B. T.

Action of Potassium and Sodium Arsenates on Metallic Sesquioxides. By C. LEFÈVRE (*Compt. rend.*, **111**, 36—38; compare this vol., p. 562).—*Alumina*.—Potassium metarsenate with 6 to 7 per cent. of the oxide yields a pyroarsenate, $2Al_2O_3,3As_2O_5$, in small, colourless, transparent prisms, which have longitudinal extinctions and two very widely separated axes. With more than 7 per cent. of alumina, the product is an arsenate, $2Al_2O_3,3K_2O,3As_2O_5$, analogous to the phosphate formed under similar conditions; it crystallises in colourless, striated lamellæ, with longitudinal extinctions. The addition of 20 per cent. of potassium chloride to the mixture promotes the crystallisation of this compound, but a higher proportion yields an almost amorphous product.

Potassium pyroarsenate and orthoarsenate, with sufficient potassium chloride to give a fluid mass, yield only amorphous products.

Sodium metarsenate yields the compound $2Al_2O_3,3As_2O_5$, but with more than 8 per cent. of alumina the compound $2Al_2O_3,3Na_2O,3As_2O_5$ is also obtained, and the latter is the sole product if about 20 per cent. of sodium chloride is present. It forms transparent lamellæ with longitudinal extinctions. With a large proportion of sodium chloride, or with the pyro- and ortho-arsenate, the results are similar to those obtained with the potassium salts.

Chromic Oxide.—The results are precisely similar to those obtained with alumina, and the products are $2Cr_2O_3,3As_2O_5$, which forms transparent, green prisms, sometimes elongated, sometimes flattened, with oblique extinctions; $2Cr_2O_3,3K_2O,3As_2O_5$, which separates in macled, transparent, green prisms, which show longitudinal extinctions and are probably monoclinic; and $2Cr_2O_3,3Na_2O,3As_2O_5$, which crystallises in transparent, green, rhomboidal dodecahedra.

Ferric Oxide.—Potassium metarsenate and about 7 per cent. of the oxide yield the pyroarsenate, $K_2O,Fe_2O_3,2As_2O_5$, in colourless, transparent, rhombic prisms, which act strongly on polarised light. Sodium metarsenate yields the salt, $Na_2O,Fe_2O_3,2As_2O_5$, in greenish, transparent prisms. In other respects, the results are analogous to those obtained with alumina and chromic oxide. The compound $2Fe_2O_3,3K_2O,3As_2O_5$ forms large, greenish, strongly macled lamellæ, and the compound $2Fe_2O_3,3Na_2O,3As_2O_5$ forms transparent, green, monoclinic prisms.
C. H. B.

Chromiodates. By A. Berg (*Compt. rend.*, **111**, 42—43).—The author has previously described (Abstr., 1887, 776) chromiodic acid and its potassium, sodium, ammonium, and lithium salts, the potassium compound being identical with the product obtained by Blomstrand (this vol., p. 107). He has also prepared several other salts. *Magnesium chromiodate*, obtained in somewhat brownish-red, crystalline crusts by treating magnesium oxide or carbonate with excess of chromic acid, and then adding two molecular proportions of iodic acid for each molecular proportion of magnesium oxide. *Cobalt chromiodate*, obtained in a similar manner, has a similar appearance, but if kept for a long time over sulphuric acid, it loses water, and yields a violet-brown, crystalline powder. *Nickel chromiodate* is obtained in a similar manner in well-developed, brownish-yellow crystals, which seem to contain 3 mols. H_2O. The *silver salt* cannot be obtained in the same way, because silver iodate separates. Silver nitrate is dissolved in nitric acid, and chromic anhydride (1 mol.) is added. Silver chromate separates, and powdered iodic acid (1 mol.) is then added, and the liquid boiled until the chromate is changed into the paler chromiodate, which is washed with alcohol and recrystallised from boiling nitric acid. It forms a brilliant, crystalline, bright-red powder of the composition $AgO{\cdot}CrO_2{\cdot}O{\cdot}IO_3$, and is only slightly attacked by cold water, but is rapidly decomposed by boiling water. The *copper salt* is obtained in the same way, and is very soluble in boiling nitric acid, from which it separates in yellowish-brown, soft crystals on cooling. Slow concentration of the nitric acid solution yields larger crystals, and if they are gently heated they lose water and acquire a cinnabar-red colour. When exposed to air, the copper salt absorbs water and decomposes, and if treated with water it at once splits up into chromic acid and cupric iodate. C. H. B.

Double Phosphates of Tin, Titanium, and Copper. By L. OUVRARD (*Compt. rend.*, **111**, 177—179; compare this vol., p. 1055).—*Titanium dioxide*, with a large excess of potassium metaphosphate, yields cubo-octahedrons of the phosphate TiO_2,P_2O_5, identical with those obtained by Hautefeuille and Margottet by the action of phosphoric acid. With a higher proportion of titanic oxide, the phosphate $K_2O,4TiO_2,3P_2O_3$ is obtained in small, highly refractive, almost cubic crystals, isomorphous with the corresponding sodium salt. Potassium pyrophosphate or orthophosphate yields a basic salt, $K_2O,2TiO_2,P_2O_5$, in biaxial crystals, probably monoclinic, but closely resembling regular octahedra. With other proportions of titanic oxide, acicular crystals of rutile are obtained, and these crystals are formed instead of the double phosphate if an excess of potassium chloride is present. Sodium metaphosphate gives the phosphate described by Wunder, $Na_2O,4TiO_2,3P_2O_5$, in highly birefractive rhombohedra of 91° 22′, with diagonal extinctions. The phosphate obtained by Knop under these conditions, TiO_2,P_2O_5, was also obtained, and with other proportions, acicular crystals of rutile were formed, but, contrary to the statement of Rose, no anatase. Sodium pyrophosphate or orthophosphate yields the salt $6Na_2O,3TiO_2,4P_2O_5$, in macled, striated prisms, with longitudinal extinctions.

Stannic oxide, with potassium metaphosphate, yields the salt $K_2O,4SnO_2,3P_2O_5$, isomorphous with the corresponding titanium compound. No cassiterite is obtained. Potassium pyrophosphate or orthophosphate yields crystals of the salt $K_2O,2SnO_2,P_2O_5$, similar to those of the analogous titanium compound, but more highly birefractive. With sodium metaphosphate, the author obtained the salts $Na_2O,4SnO_2,3P_2O_5$ and Na_2O,SnO_2,P_2O_5, described by Wunder, and SnO_2,P_2O_5, described by Knop, but not the salt $2SnO_2,P_2O_5$, obtained by the latter.

Cupric oxide or carbonate, with potassium metaphosphate, yields large, greenish-blue, probably monoclinic lamellæ of the salt $K_2O,8CuO,3P_2O_5$. Potassium pyrophosphate yields the compound $K_2O,2CuO,P_2O_5$, in pale-blue crystals with oblique extinctions. Potassium orthophosphate yields the same salt together with some crystals of cuprite if the proportion of cupric oxide is considerable. Sodium metaphosphate yields, as Wallroth has already stated, dichroic prisms, probably monoclinic, of the salt $3Na_2O,3CuO,2P_2O_5$. With an excess of cupric oxide, or with sodium pyrophosphate, the salt $Na_2O,2CuO,P_2O_5$ is obtained in prisms with oblique extinctions. Sodium orthophosphate produces a mixture of cupric and cuprous oxides, together with amorphous matter.

Titanic, stannic, and cupric oxides are characterised by double phosphates of the formulæ $Na_2O,4MO_2,3P_2O_5$ and $6Na_2O,3MO_2,4P_2O_5$.

C. H. B.

Arsenovanadic Acids. By C. FRIEDHEIM and W. SCHMITZ-DUMONT (*Ber.*, **23**, 2600—2608; compare this vol., p. 1066).—The compound prepared by Berzelius by oxidising vanadyl arsenate, $V_2O_4,2As_2O_5 + 3H_2O$, with nitric acid, is identical with the vanadium arsenate obtained by Fernandez, and has not, therefore, the composition $2V_2O_5,3As_2O_5$ assigned to it by Berzelius.

Vanadium arsenate, $V_2O_5,As_2O_5 + 10H_2O$, is also formed when a concentrated solution of arsenic acid is boiled with excess of vanadic hydrate. It gradually loses some of its water of crystallisation on exposure to the air, and, when kept over sulphuric acid or heated at 100°, about 9 mols. of water are eliminated; it is converted into the anhydrous salt at about 440° without decomposition, but aqueous solutions of a certain concentration are decomposed at 100° with elimination of vanadic hydrate; it separates from nitric acid in crystals containing 2 mols. H_2O.

Compounds of the general formula $2R''O.2V_2O_5,3As_2O_5$ can be obtained by dissolving the carbonates of the metals $R''CO_3$ in excess of vanadium arsenate and evaporating the solution over sulphuric acid. The following orange-red, crystalline salts were prepared in this way.

$$2ZnO,2V_2O_5,3As_2O_5 + 23H_2O,$$
$$2CaO,2V_2O_5,3As_2O_5 + 21H_2O,$$
$$2SrO,2V_2O_5,3As_2O_5 + 20H_2O.$$

The crystalline salts of the composition $2MgO,2V_2O_5,3As_2O_5 + 23H_2O$ and $2(NH_4)_2O,2V_2O_5,3As_2O_5 + 4H_2O$ were prepared by treating magnesium and ammonium vanadate respectively with excess of arsenic acid.

The compounds

$$ZnO,V_2O_5,As_2O_5 + 6\tfrac{1}{2}H_2O,$$
$$CuO,V_2O_5,As_2O_5 + 4H_2O,$$
$$CoO,V_2O_5,As_2O_5 + 9H_2O,$$
$$MgO,V_2O_5,As_2O_5 + 10H_2O$$

were also obtained by treating the normal vanadates with arsenic acid and by various other methods.

The salt $5(NH_4)_2O,2V_2O_5,4As_2O_5 + 19H_2O$, described by Ditte, has no existence, but the compounds $(NH_4)_2O,2V_2O_5,As_2O_5 + 5H_2O$ and $K_2O,2V_2O_5,As_2O_5 + 5H_2O$ can be easily prepared in various ways; both substances crystallise in microscopic needles, and lose the whole of their water at 100°.

F. S. K.

Thiovanadates. By G. Krüss and K. Ohnmais (*Ber.*, **23**, 2547—2552).—*Ammonium thiovanadate*, $(NH_4)_3VS_4$, is deposited in crystals when hydrogen sulphide is passed for several hours into an ice-cold saturated solution of ammonium metavanadate in ammonium hydrate of sp. gr. 0·898, and the dark-violet solution obtained in this way is kept for some days. It can be more conveniently prepared by adding a solution of ammonium hydrosulphide to a solution of potassium metavanadate or sodium pyrovanadate; after a comparatively short time, ammonium thiovanadate separates from the solution in rhombic crystals, $a : b : c = 0·9825 : 1 : 1·742$, similar in appearance to those of potassium permanganate; its sp. gr. is 1 6202.

Ammonium pyroxyhexathiovanadate, $(NH_4)_4V_2S_6O$, is formed when hydrogen sulphide is passed into a solution of ammonium metavanadate in ammonium hydrate of greater sp. gr. than 0·898; on keeping the red solution for some months at a low temperature, a considerable quantity of the salt is deposited in crystals. It is rather darker in colour than the normal salt described above, and its sp. gr. is 1·7155.

The corresponding *potassium* salt, $K_4V_2S_6O + 3H_2O$, can be prepared by treating an ice-cold solution of potassium vanadate in potash of sp. gr. 1·472 with hydrogen sulphide in absence of air; after a long time, the salt separates from the solution in crystals resembling those of freshly-prepared potassium permanganate; it has a sp. gr. of 2·1443. When carefully heated at 150°, it is converted into the anhydrous salt, but if heated too quickly, it melts to a cherry-red liquid, and, on continued heating, is decomposed with liberation of sulphur.

A salt of the composition $K_8V_4S_{12}O_2 + 3H_2O$ is obtained in large crystals when the mother liquors from the preceding compound are evaporated over phosphoric anhydride; its sp. gr. is 2·1195.

Several double salts, or mixtures of potassium and ammonium thiovanadate, were prepared by treating a solution of potassium vanadate in potash with hydrogen sulphide, and then mixing it under different conditions with a solution of ammonium thiovanadate in ammonium hydrosulphide; the analyses of these mixtures showed that they contained the normal ammonium salt, and most probably also the normal potassium salt K_3VS_4.

Sodium orthoxytrithiovanadate, $Na_3VS_3O + 5H_2O$, is deposited in crystals when a solution of sodium hydrate of sp. gr. 1·122 (30 c.c.) is saturated with hydrogen sulphide, mixed with an aqueous solution (6 c.c.) of sodium pyrovanadate (3 grams), and hydrogen sulphide passed through the ice-cold mixture for four hours; it forms small, dark reddish-brown, very deliquescent crystals, and gradually loses the whole of its water when heated.

Sodium orthoxythiovanadate, $Na_3VSO_3 + 10H_2O$, is precipitated as an oil when freshly-prepared sodium hydrosulphide is added to a boiling solution of sodium pyrovanadate, the mixture boiled for a short time, and the ice-cold, filtered solution treated with alcohol (3 vols.); after being repeatedly washed with cold alcohol, it solidifies to a mass of orange-red crystals. It melts at 18°, and its sp. gr. is 1·7727.

F. S. K.

Rhodium Nitrites. By E. LEIDIÉ (*Compt. rend.*, **111**, 106—109). —A solution of rhodium chloride or of rhodium potassium chloride is slightly acidified with hydrochloric acid, diluted until it contains not more than 5 grams of rhodium per litre, heated to boiling, and mixed with successive small quantities of potassium nitrite until the solution is decolorised, and a slight turbidity appears. The liquid is allowed to cool, and the crystals which separate are washed with cold water and dried at 105°.

The potassium rhodium nitrite thus obtained, $Rh_2(NO_2)_6,6KNO_2$, forms white, microscopic crystals which do not act on polarised light; it is almost insoluble in cold water, only slightly soluble in boiling water, and quite insoluble in alcohol, in a solution containing an excess of potassium nitrite, and in a 30 per cent. solution of potassium chloride, or a 50 per cent. solution of potassium acetate. It is slowly decomposed by cold concentrated mineral acids, and more rapidly on heating. With hydrochloric acid, it yields the double chloride $Rh_2Cl_6,6KCl + 3H_2O$, obtained by Claus, but if this is treated with potassium chloride, it is converted into the salt $Rh_2Cl_6,4KCl$, which is more stable, and which is the only double salt formed by the crystallisation of a mixed solution of potassium and rhodium chlorides.

The sodium salt is analogous in composition, and is prepared in a similar manner, but the solution must be mixed with an equal volume of alcohol of 90°. It forms white, somewhat bulky crystals, which act on polarised light. It dissolves in 2·5 parts of water at 17°, and in 1 part of boiling water, but is insoluble in alcohol. An aqueous solution of the salt does not give the ordinary reactions of rhodium; it yields no precipitate with sodium hydroxide or carbonate, and with potassium or ammonium hydroxide or carbonate no precipitate of rhodium oxide is formed, but the insoluble potassium rhodium or ammonium rhodium nitrite separates. Hydrogen sulphide or sodium sulphide will, however, precipitate rhodium sulphide, slowly in the cold, more rapidly on heating. The sodium salt is readily attacked by mineral acids, especially on heating, and with hydrochloric acid it yields the chloride $Rh_2Cl_6,6NaCl + 18H_2O$.

The ammonium salt cannot be prepared directly in consequence of the ready decomposition of ammonium nitrite, but it is obtained by adding ammonium chloride to a solution of the sodium salt. It separates in white, microscopic crystals which have no action on polarised light. In solubility and behaviour towards acids it is precisely similar to the potassium salt; with hydrochloric acid, it yields the salt $Rh_2Cl_6,6NH_4Cl + 3H_2O$.

The barium salt, $Rh_2(NO_2)_6,3Ba(NO_2)_2 + 12H_2O$, is obtained in the same way as the sodium and potassium compounds, and separates in somewhat bulky, white crystals, soluble in 50 parts of water at 16°, and in 6·5 parts of boiling water. The crystals have no action on polarised light. With hydrochloric acid, the salt yields a mixture of rhodium and barium chlorides, which, however, will not form a double salt, and if the barium is precipitated by sulphuric acid, the rhodium chloride can be obtained quite free from alkaline chlorides. A solution of barium rhodium nitrite behaves towards potassium and ammonium salts like the double sodium nitrite; with sodium hydroxide or carbonate, a precipitate of the corresponding barium compound is obtained, but all the rhodium remains in solution in the form of the double sodium salt.

The insolubility of potassium rhodium nitrite can be utilised for the preparation of pure rhodium, its separation from other metals of the platinum group, and its quantitative estimation.

C. H. B.

Double Salts of Rhodium. By K. SEUBERT and K. KOBBÉ (*Ber.*, **23**, 2556—2561).—Potassium rhodium chloride, $Rh_2Cl_6,4KCl + 2H_2O$, is deposited in deep-red crystals when spongy rhodium (1 part) is fused with potassium chloride (2 parts) in a stream of chlorine. and the filtered aqueous solution of the product evaporated under reduced pressure. If the mother liquors are then saturated with hydrogen chloride to precipitate the potassium chloride and the filtered solution again evaporated, a new salt is obtained in dark-red, sparingly soluble crystals, which become cloudy and lighter in colour when kept over phosphoric anhydride, and have then the composition $Rh_2Cl_6,6KCl + 3H_2O$.

Sodium rhodium sulphite, $4RhSO_3,6Na_2SO_3 + 9H_2O$, is obtained when a solution of rhodium chloride is heated for some time with excess of sodium hydrogen sulphite, the precipitate washed with cold water and dried over phosphoric anhydride. It is only very sparingly soluble in hot water, but it dissolves freely in nitric acid with evolution of sulphurous anhydride.

Sodium rhodium sulphate has been previously obtained by Bunsen (*Annalen*, **146**, 265), by heating the sulphite just described with concentrated sulphuric acid; it has the composition $Rh_2(SO_4)_3,Na_2SO_4$.

F. S. K.

Iridium Phosphorus Bromides. By G. GEISENHEIMER (*Compt. rend.*, **111**, 40—41).—1 gram of hydrated iridium dioxide is mixed with 10 grams of bromide, and phosphorus tribromide added gradually until the whole mass becomes solid. The tube is then sealed and heated for two to three hours at 150°; the hydrobromic acid is allowed to escape, the tube is re-sealed and then heated for 24 hours at 300°. A deep-red liquid is thus obtained which solidifies in confused red and yellow crystals. The tube is now heated in a vertical position for two to three hours at 100°, and is gradually inverted in order to separate the liquid from the red crystals, which are washed with boiling carbon bisulphide; they are red needles and have the composition $Ir_2Br_6,6PBr_3$.

When treated with water they are partially attacked and yield an acid solution and a black substance with a red lustre, which is soluble in water with difficulty and has the same composition as the original crystals. If the compound is heated with phosphorus tribromide in sealed tubes at 200° it yields the compound $Ir_2Br_6,4PBr_3$ in black crystals, and it follows that excess of the tribromide should be avoided in the preparation of the first substance.

Attempts to obtain a bromine compound analogous to $Ir_2P_6Cl_{0}$ gave negative results. When the bromide, $Ir_2P_6Br_{24}$, is heated in sealed tubes with bromine, it yields phosphorus pentabromide and the compound $Ir_2P_4Br_{18}$. A mixture of phosphorus pentabromide, the compound $Ir_2P_6Br_{24}$, and phosphorus oxychloride behaves in a similar manner. If the chloride $Ir_2P_5Cl_{30}$ is heated at 300° with PBr_3, it yields only a mixture of the chloride $Ir_2P_6Cl_{24}$, the bromide $Ir_2P_4Br_{18}$, and phosphorus chlorobromide. If, however, a mixture of the bromide $Ir_2P_6Br_{24}$, phosphorus pentabromide, and phosphorus trichloride is heated, a compound $Ir_2Br_8,4PCl_3$ is obtained, and this indicates the possible existence of a perbromide.

The difficulty experienced in preparing the higher bromides is probably due partly to the reducing action of the phosphorus tribromide, observed by Lindet in the cause of gold phosphorus perbromide, and partly to the instability of phosphorus pentabromide.

The iridium phosphorus chlorides and bromides differ in that the most stable chloride has the composition $Ir_2P_6Cl_{24}$, and the most stable bromide the composition $Ir_2P_4Br_{18}$.

The author has analysed the acid $Ir_2Br_6,6H_3PO_3$ and its potassium and lead salts. C. H. B.

Mineralogical Chemistry.

Artificial Production of Boracite in the Wet Way. By A. DE GRAMONT (*Compt. rend.*, 111, 43—44).—1 part of sodium borate, 2 parts of magnesium chloride, and a small quantity of water are heated in sealed tubes at 275—280°. The product, after being separated by levigation from the amorphous magnesium borate, is a white, crystalline powder, which scratches glass. It consists of microscopic birefractive tetrahedra, cubo-tetrahedra, and pyramidal tetrahedra; sp. gr. = 2·89, that of the natural mineral being 2·90. The composition of the product agrees closely with that of natural boracite and is as follows:—MgO, 27·26; B_2O_3 (calc.), 63 86; Cl, 7·71; Mg, 2·60 = 101·43. C. H. B.

Normal Aluminium Sulphate. By P. M. DELACHARLONNY (*Compt. rend.*, 111, 229—231).—The author has examined some finely-crystallised specimens of native aluminium sulphate from Bolivia. They were covered with a white, amorphous crust, but the interior consisted of translucent, prismatic crystals of the composition $Al_2(SO_4)_3 + 16H_2O$, and are, therefore, identical in their degree of hydration with the artificial product (Abstr., 1884, 820).

C. H. B.

Meteoric Iron from Magura, Hungary. By BERTHELOT and FRIEDEL (*Compt. rend.*, 111, 296—300).—The meteoric iron examined weighed 280 grams, and was obtained from Magura, in Arva, Hungary. In order to ascertain whether it contained any diamonds, it was repeatedly treated with aqua regia, and the matter remaining undissolved was treated with nitric acid and potassium chlorate. After combustion of the graphitic acid, there was left a small quantity of a white, crystalline powder, which scratched rubies. It did not disappear on treatment with ammonium fluoride and sulphuric acid, and did not burn when heated under such conditions that small fragments of diamond burnt away completely. Optical examination and determination of the sp. gr. showed that the substance had all the properties of quartz. C. H. B.

Mineral Waters of Cransac (Aveyron). By A. Carnot (*Compt. rend.*. **111**, 192—195).—These springs rise in the Valley of Cransac below the outcrop of beds of coal surmounted by carbonaceous schists containing pyrites. They do not rise from any great depth, but must be regarded as rain water which has come in contact with mineralising strata comparatively near the surface. The following table gives the quantities of the various compounds per litre :—

Carbonates are present in very small quantities, but sulphates exist in large proportions. The sulphuric acid is doubtless derived from pyrites, but the iron has been almost entirely removed by the passage of the water over magnesium limestones. The nitrates are probably derived from ammonium compounds produced from the coal by the action of the subterranean fires which are known to occur in the district. C. H. B.

Organic Chemistry.

Hydrates of Gases. By VILLARD (*Compt. rend.*, **111**, 302—305). —Propane was purified from air and hydrogen by liquefying the gas and then opening the reservoir at the top. The air and hydrogen escaped, and when the liquid propane had risen to the aperture, the pressure inside the apparatus was made to coincide with the atmospheric pressure, and the aperture was sealed up.

In order to obtain the propane hydrate, part of the tube must be momentarily cooled below 0°; crystals separate and continue to form at temperatures higher than 0°, until all the liquid propane has disappeared. The tension of dissociation of the hydrate at 0° is about 1 atmos., but it can be preserved indefinitely under suitable pressure at temperatures below 8·5°. At 8·5°, it decomposes, whatever the pressure, and this temperature is not altered by the presence of air. It is noteworthy that, in the methane series, the critical temperature of the formation of the hydrates is lower, the higher the molecular weight of the hydrocarbon.

Carbon fluorides form hydrates under similar conditions, the critical temperatures being as follows: carbon tetrafluoride, +20·4°; carbon difluoride, +10·5°; methylene fluoride, +17·6°; and trifluoromethane, +21·8°. C. H. B.

Hydrates of Haloïd Alkyl Salts. By VILLARD (*Compt. rend.*, **111**, 183—185).—The hydrates were formed under the same conditions as the hydrate of methyl chloride (Abstr., 1888, 644 and 897). The hydrate of ethyl fluoride can be kept under pressure at the ordinary temperature for many hours; hydrate of methyl fluoride decomposes at 13·8°; hydrate of ethyl chloride forms acicular crystals, 2 or 3 mm. long, which decompose at 5°, even under a pressure of 2 atmos., and the hydrate of methyl iodide also decomposes at 4·8°.

The following tables give the tension in atmospheres of the hydrates of the alkyl fluorides.

C. H. B.

Geometrical Isomerides of the Hexamethylene Derivatives. By H. SACHSE (*Ber.*, **23**, 1363—1370).—Starting from the hypotheses that the four affinities of a carbon atom are directed from the centre to the solid angles of a regular tetrahedron, and that two carbon atoms which are united by a single bond will tend so to place themselves that the directions of the two combining affinities fall in one and the same straight line, the author comes to the conclusion that, although in rings of three, four, or five carbon atoms, the centres of the tetrahedra may all lie in the same plane, this is no longer possible with rings containing a larger number of carbon atoms. In the case of hexamethylene, if the centres of contiguous carbon atoms be united by straight lines, then a broken line in space will thus be formed. According to the conditions of the above hypotheses, this broken line must consist of six straight lines, equal in length, and which meet each other at angles of 109° 28′. These conditions, which lead to a system of three equations, can be satisfied by two different configurations, which are found to resemble and bear a very simple relation to the configuration of the benzene molecule formerly described by the author (Abstr., 1888, 1181). By the aid of the formulæ thus arrived at, the isomerism which has been observed in the case of the hexahydromellitic and the hexahydroterephthalic acids may be easily explained and represented. H. C.

Nitroprussides. By PRUD'HOMME (*Compt. rend.*, **111**, 45—46).—When an aqueous solution of an alkaline nitrite and an alkaline ferricyanide is boiled, the latter salt is partially converted into a nitroprusside. By using the azosulphonates (obtained by the action of sodium nitrite on sodium hydrogen sulphite), very concentrated solutions of nitroprussides can be obtained. 34·5 grams of sodium nitrite, dissolved in 150 grams of water at 70°, is mixed with 216 grams of sodium hydrogen sulphite of 37° B. and a solution of 82 grams of potassium ferricyanide in 250 grams of water at 70°. The mixture is boiled until evolution of gases ceases, and the cooled liquid, which already contains much nitroprusside, is gradually mixed with 54 grams of sodium hydrogen sulphite of 37° B. The deep red liquid thus obtained contains a very large quantity of the nitroprusside. With the same quantity of nitrite, the yield varies with the proportions of sulphite and ferricyanide. The results are also different if the first stage of the operation is conducted at a low temperature. Under these conditions, if a sufficient quantity of sulphite is present, no nitrogen oxides are evolved. With proportions of sulphite and ferricyanide slightly different from those given, the solution of nitroprusside, after a time, deposits white, silky crystals, only very slightly soluble in water. They frequently decompose whilst in a moist state on the filter, and are at once decomposed by boiling water into Prussian blue and sulphuric acid. They seem to be identical with the product obtained by dissolving Prussian blue in concentrated sulphuric acid.

If an aqueous solution of 34·5 parts of sodium nitrite, 15·5 parts of sodium thiosulphate, and 41 parts of potassium ferricyanide is boiled, the ferricyanide is gradually converted into nitroprusside, the yield of the latter being greater than if the thiosulphate were not present. The liquid also deposits a brown substance, which dissolves in concentrated hydrochloric acid, and if water is added to this solution, Prussian blue is precipitated, and the liquid contains ferric chloride.

When a nitroprusside is added to the yellow solution obtained by boiling sulphur with sodium hydroxide solution of 36° B., a beautiful dichroic solution is obtained, purple by transmitted light, and blue by reflected light. C. H. B.

Tertiary Butyl Carbinol. By M. Freund and F. Lenze (*Ber.*, **23**, 2865—2869).—*Trimethylacetamideoxime*, $CMe_3\cdot C(NH_2)\colon NOH$, is prepared from trimethylacetonitrile, and melts at 115—116°; the corresponding *phenylamidine oxalate* melts at 192°. *Tertiaryamylamine*, $CMe_3\cdot CH_2\cdot NH_2$, is formed by the reduction of the nitrile with sodium in alcoholic solution; it boils at 82—83°, and rapidly absorbs carbonic anhydride on exposure to the air. The *platinochloride* crystallises in pale-yellow plates; the *aurochloride* is deposited in lemon-yellow needles. *Amylcarbamide*, $CMe_3\cdot CH_2\cdot NH\cdot CO\cdot NH_2$, is obtained by the action of potassium cyanate; it crystallises from ether in small needles melting at 145°. *Phenylamylcarbamide*,

$$CMe_3\cdot CH_2\cdot NH\cdot CO\cdot NHPh,$$

crystallises from alcohol in white needles, which melt at 155°. *Phenylamylthiocarbamide*, $CMe_3\cdot CH_2\cdot NH\cdot CS\cdot NHPh$, melts at 136°. *Diamyloxamide*, $CMe_3\cdot CH_2\cdot NH\cdot CO\cdot CO\cdot NH\cdot CH_2\cdot CMe_3$, is formed by the action of ethyl oxalate on the amine; it crystallises from ether in needles melting at 165°. *Tertiary butyl carbinol*, $CMe_3\cdot CH_2\cdot OH$, is prepared by the action of silver nitrite on the hydrochloride of the amine; it is a colourless liquid with a camphor-like odour, has a sp. gr. of 0·8122 at 20°, boils at 102—103°, and is somewhat soluble in water. During the preparation of trimethylacetonitrile, Butlerow obtained a compound to which he gave the formula $CMe_3\cdot NH\cdot CHO$; the authors have also observed the formation of this substance, but their analyses show that it contains no oxygen. J. B. T.

Amyl Alcohol in Brandy from different parts of the German Empire. By Sell (*Ann. Agronom.*, **16**, 335—336).—The quantity varied from 0·641 to 0·016 per 100 parts of ethyl alcohol, that is, 0·256—0·006 per cent. of the brandy of commerce. J. M. H. M.

Mannitol Hexachlorhydrin. By L. Mourgues (*Compt. rend.*, **111**, 111—113).—Mannitol is heated for several hours at a temperature not exceeding 145° with seven times its weight of phosphorus pentachloride containing a small quantity of the oxychloride. When evolution of hydrogen chloride ceases, the phosphorus oxychloride is distilled off at a temperature not exceeding 145°, and the syrupy product is gradually poured into ice-cold water, and is then distilled in a current of steam. The first portion of the distillate contains a mixture of chlorine and oxygen derivatives of mannitol and mannitan, after which mannitol hexachlorhydrin, $C_6H_8Cl_6$, passes over. It crystallises in odourless, small, white, nacreous leaflets, which melt and volatise at 137·5°. It boils at 180—185° under a pressure of 30 mm., and is insoluble in water, slightly soluble in alcohol, and very soluble in ether, benzene, chloroform, light petroleum, &c. Its sp. gr. is 2·060, and its rotatory power in a benzene solution at 20° is $[\alpha]_D = +18° 32'$. It is not dissolved by boiling concentrated alkalis, but dissolves in hot sulphuric acid, from which it separates on cooling. The molecular weight as determined by Raoult's method agrees with the formula $C_6H_8Cl_6$, and there is little doubt that the compound has the constitution $CH_2Cl·[CHCl]_4·CH_2Cl$. C. H. B.

Conversion of Glucose into Sorbite. By J. MEUNIER (*Compt. rend.*, **111**, 49—51).—Glucose is dissolved in twice its weight of water, and mixed with excess of sodium amalgam containing 2·5 per cent. of sodium, great care being taken to avoid a rise of temperature. The liquid is acidified with sulphuric acid, neutralised with barium carbonate, filtered, concentrated, and mixed with alcohol, in order to precipitate sodium sulphate, and the concentrated alcoholic filtrate is mixed with hydrochloric acid and benzaldehyde. Sorbite separates in the form of its dibenzoic acetal. If the acid and the benzaldehyde are not added in excess, the acetal separates chiefly in the soluble form (this vol., p. 731), but if excess of the reagents is employed, the greater part of the acetal is insoluble.

If the glucose is dissolved in four or five times its volume of water, and the sodium hydroxide which is formed is continually neutralised by the addition of sulphuric acid, only a very small quantity of sorbite is obtained. C. H. B.

Hydrogenation of Sorbin and the Oxidation of Sorbite. By C. VINCENT and DELACHANAL (*Compt. rend.*, **111**, 51—53).—If a 33 per cent. solution of sorbin is mixed with successive small quantities of sodium amalgam containing 2 per cent. of sodium, care being taken to avoid a very great rise of temperature, the sorbin is converted into sorbite, which can be isolated in the form of its dibenzoic acetal after neutralisation with sulphuric acid and the precipitation of the sodium sulphate by alcohol.

When sorbite is oxidised by heating it with bromine-water at 60° in a sealed tube, it yields a glucose which can be isolated in the form of a phenylglucazone, but the authors have not yet determined whether it is dextrose or levulose. C. H. B.

Optical Isomerides of Grape-sugar, Gluconic Acid, and Saccharic Acid. By E. FISCHER (*Ber.*, **23**, 2611—2624; compare this vol., pp. 466, 1223, and 1230).—l-Mannonic acid (arabinosecarboxylic acid) can be partially converted into the optically isomeric l-gluconic acid by heating it with quinoline, just as d-mannonic acid can be transformed to a certain extent into gluconic acid; l-gluconic acid, on reduction, yields l-glucose, the optical isomeride of grape-sugar, and both compounds, on oxidation with nitric acid, are converted into l-saccharic acid.

The members of the l-series resemble the known compounds of the d-series very closely, and combine with them to form the corresponding inactive substances, namely i-glucose, i-gluconic acid, and i-saccharic acid.

l-Gluconic acid is most conveniently prepared from arabinose in the following manner:—A solution of arabinose (50 grams) in warm water (55 grams) is treated with hydrogen cyanide (10 grams), as described by Kiliani (Abstr., 1887, 229), the crystalline amide which separates from the solution in the course of three to eight days is boiled with crystalline barium hydroxide (100 grams) and water (250 grams) until the evolution of ammonia ceases, and the barium is then exactly precipitated with sulphuric acid. On evaporating the solution, previously decolorised with animal charcoal, to a thick syrup, the greater part of the l-mannonic acid separates in the form of the lactone; the mixture is agitated with a little 96 per cent. alcohol, filtered, and the residual lactone washed repeatedly with a little cold alcohol and then purified by recrystallisation from the hot solvent. The alcoholic filtrate and washings are evaporated on the water-bath, the l-mannolactone, which is deposited in the course of one to two days, separated as before, and the alcoholic liquors again evaporated. The syrup obtained in this way contains the whole of the l-gluconic acid and small quantities of l-mannonic acid; it is dissolved in water (4 parts) and warmed for an hour with phenylhydrazine (1 part) and 50 per cent. acetic acid (0·75 part); on cooling, a mixture of the two hydrazides separates from the solution in yellow crystals. This precipitate is separated by filtration, washed with cold water, alcohol, and ether consecutively, and then decomposed with barium hydroxide; the solution, freed from phenylhydrazine and barium in the usual way, is decolorised with animal charcoal, concentrated by evaporation, boiled with calcium carbonate until neutral, and then treated again with animal charcoal. The mixture of the two calcium salts which remains when the solution is evaporated is dissolved in a little hot water. and alcohol added until a turbidity is produced; on cooling, the calcium salt of l-gluconic acid is deposited as a syrup which gradually solidifies, and can then be obtained in a pure condition by recrystallisation from warm water. Having once obtained crystals of the pure calcium salt, it is unnecessary to purify the acid by means of its hydrazide; the crude syrup which is left after separating the l-mannolactone as completely as possible is dissolved in water, the boiling solution neutralised with calcium carbonate, decolorised with animal charcoal, and a small quantity of the crystalline calcium salt introduced into the concentrated solution; after a few days, a large quantity of calcium gluconate is deposited in crystals, and the salt can then be further purified by recrystallisation from warm water. 50 grams of arabinose yield 8 to 9 grams of pure calcium l-gluconate, together with about 20 grams of pure l-mannolactone.

When an aqueous solution of l-gluconic acid, obtained by decomposing the calcium salt with the theoretical quantity of oxalic acid, is boiled, the acid is partially converted into the lactone, and, on evaporating, the two compounds remain as a syrup from which crystals have not yet been obtained; the aqueous solution of this syrup is levo-rotatory. The *calcium* salt, $(C_6H_{11}O_7)_2Ca$, separates from hot water in cauliflower-like crystals, similar in appearance to those of calcium d-gluconate; it is soluble in 3 to 4 parts of hot water, and its specific rotatory power is $\alpha_D \frac{20}{4} = -6\cdot64°$. A *basic* salt is formed when calcium hydroxide is added to a lukewarm aqueous solution of the neutral salt; on cooling the filtered solution, it is deposited in a flocculent condition. The barium, strontium, and cadmium salts are readily soluble in water, and have not yet been obtained in crystals.

The *hydrazide*, $C_6H_{11}O_6 \cdot N_2H_2Ph$, crystallises from hot water in small, colourless plates or prisms, and when quickly heated melts at about 200° with decomposition.

l-Gluconic acid can be most readily distinguished from d-gluconic acid by converting both compounds into the corresponding lactones, and then submitting the solutions to an optical examination; the acid is best identified by converting it into l-saccharic acid in the manner described below.

l-Mannonic acid can be detected in presence of l-gluconic acid by reducing the sample with sodium amalgam, and treating with phenylhydrazine the cold, concentrated aqueous solution of the sugar produced; if l-mannose is present, even in small quantity, the hydrazone is precipitated in crystals in a few hours' time.

l-Gluconic acid is formed, as has been stated above, when l-mannonic acid is heated with quinoline at 140° for an hour, but this method is not suitable for the preparation of the acid; a large quantity of mannonic acid remains unchanged, and the gluconic acid is not easily obtained in a pure condition. l-Gluconic acid, under the same conditions, is partially converted into l-mannonic acid.

i-Gluconic acid has properties similar to those of its components; on evaporating its aqueous solution, there remains a colourless syrup which consists of a mixture of acid and lactone. The *calcium* salt, $(C_6H_{11}O_7)_2Ca$, is deposited in crystals when a solution of equivalent parts of calcium d- and l-gluconate is slowly evaporated on the water-bath; when dried at 100°, it seems to contain 1 mol. H_2O. It is soluble in 16 to 20 parts of boiling water, and, like the acid and the lactone, is optically inactive. The *hydrazide*, $C_6H_{11}O_6 \cdot N_2H_2Ph$, can be obtained by heating the acid or the calcium salt with phenylhydrazine acetate; it separates from hot water in colourless crystals, melts at 188—190°, and is optically inactive.

i-Gluconic acid can also be obtained by heating i-mannonic acid with quinoline, but the change, as in the case of the other acids, is only a partial one.

l-Glucose, $C_6H_{12}O_6$, is obtained when l-glucolactone is reduced with sodium amalgam, and the solution freed from sodium salts in the usual manner; on evaporating the alcoholic solution of the sugar, there remains a syrup which gradually crystallises. It is recrystallised from water, spread on a porous plate, then dissolved in hot methyl alcohol, and the solution mixed with alcohol; after a long time, the pure compound separates from the solution in anhydrous, prismatic crystals. It resembles grape-sugar very closely in appearance, melts at 141—143°, has a sweet taste, and is very readily soluble in water, but very sparingly in alcohol. It also resembles grape-sugar in optical behaviour, and exhibits the phenomenon of multi-rotation; after 12 hours' time, the rotation has become constant, the specific rotatory power being then about $\alpha_D = -51{\cdot}4°$.

Phenylhydrazine acetate produces no precipitate in a cold aqueous solution of l-glucose, but on warming, the separation of l-phenylglucosazone quickly commences.

l-Glucosediphenylhydrazone, $C_6H_{12}O_5:N_2Ph_2$, is formed when a solution of the sugar in dilute alcohol is heated with diphenylhydrazone ($1\frac{1}{2}$ parts) for two hours at 100°. It crystallises from hot water in slender, colourless needles, and is only very sparingly soluble in cold water; it resembles the corresponding derivative of grape-sugar, and both compounds have the same melting point (162—163°).

l-Glucose, like l-mannose and l-fructose, seems not to ferment with yeast.

i-Glucose can be obtained by mixing solutions of d- and l-glucose, or by reducing i-gluconic acid with sodium amalgam. It is a colourless syrup, very readily soluble in water, but only very sparingly in alcohol, and it shows all the reactions of its components. It does not give a precipitate with phenylhydrazine acetate in the cold, but on warming, i-glucosazone is quickly deposited from the solution.

i-Glucosediphenylhydrazone, $C_6H_{12}O_5:N_2Ph_2$, prepared as described in the case of the corresponding l-derivative, separates from hot water as an oil, and then gradually solidifies to a mass of colourless, crystalline plates melting at 132—133°.

A solution of i-glucose enters into brisk fermentation with yeast; after keeping the mixture for 24 hours at 30°, fermentation is at an end, and the solution is then strongly levo-rotatory, owing to the presence of l-glucose.

l-Saccharic acid can be prepared by oxidising l-gluconic acid with nitric acid. For this purpose, the crude syrup (5 grams) which is left after separating the l-mannolactone (see above) is heated on the water-bath with nitric acid of sp. gr. 1·15 (15 grams), the residual syrup diluted with water, the solution evaporated to free it from nitric acid, then neutralised with potassium carbonate and strongly acidified with acetic acid; on evaporating to a thin syrup, the hydrogen potassium salt, $C_6H_9O_8K$, begins to separate in crystals after some time, and is purified by washing it with cold water and then recrystallising from hot water with addition of animal charcoal. The yield is 25 to 30 per cent. of the crude gluconic acid employed. It forms small needles or prisms, and is feebly levo-rotatory. The *silver* salt, $C_6H_8O_8Ag_2$, is decomposed by boiling water. The *dihydrazide*, prepared by warming the acid or the calcium salt with phenylhydrazine acetate, crystallises in almost colourless plates, and melts at 213—214° with decomposition.

The potassium hydrogen salt of l-saccharic acid is so easily recognised that its formation in the manner described above affords the best test for l-gluconic acid; l-mannonic acid, under the same conditions, does not yield a crystalline potassium hydrogen salt.

The potassium hydrogen salt of *i-saccharic acid* separates in slender needles when a hot aqueous solution of the corresponding salts of d- and l-saccharic acid is allowed to cool slowly; it is readily soluble in hot, but only sparingly in cold water, and it has the composition $C_6H_9O_8K$. The *dihydrazide* of the acid crystallises in colourless plates, and melts at 209—210° with decomposition.

i-Saccharic acid can be directly obtained by oxidising i-gluconic acid with nitric acid, and isolating the product by means of its potassium hydrogen salt in the manner described above.

The potassium hydrogen salts of the two optically active saccharic acids resemble one another very closely, and are best distinguished or identified by partially converting them into the lactones by boiling with a mineral acid, and then examining the solutions optically; the corresponding salt of i-saccharic acid can be distinguished from the other two with a little practice by its appearance simply.

As the molecule of arabinose is asymmetric, assuming that no stereometric intramolecular change occurs, there may be, in accordance with Le Bel and Van't Hoff's theory, three isomeric acids formed by treating arabinose with hydrocyanic acid, namely, two acids which with respect to the asymmetric carbon atom marked in the formula

$$CH_2(OH)\cdot[CH(OH)]_3\cdot\overset{*}{C}H(OH)\cdot COOH$$

with an asterisk, possess opposite configurations, and a third, produced by a combination of the other two, into which it can, theoretically, be resolved. Two of these three acids are represented by l-mannonic acid and l-gluconic acid, either of which may be the composite isomeride. Many attempts have been made to resolve d-mannonic acid and d-gluconic acid into two isomerides, but without success, although, as has been already shown, they are mutually convertible. It seems probable, therefore, that with reference to the C^* atom, gluconic acid and mannonic acid are the right and left forms respectively; as, however, they do not combine together to form a third acid, it would seem that such isomeric compounds do not always behave as is usually supposed. If so, the observations previously made on the configuration of the mannonic acids, the mannoses, and the mannitols with regard to this particular carbon atom are superfluous. All experience in the sugar group confirms the view that for every optically active substance there exists an isomeric form of opposite optical activity, and that the two compounds combine together to form an inactive modification; the last statement seems, however, to hold good only for the asymmetry of the whole molecule, and not for that of any single carbon atom. F. S. K.

Fucose, an Isomeride of Rhamnose. By A. GÜNTHER and B. TOLLENS (*Ber.*, 23, 2585—2586).—A crystalline sugar, which the authors name *fucose*, can be isolated from the products of hydrolysis of *fucus* by means of the hydrazone (m. p. about 170°; compare this vol., p. 1105); the pure hydrazone is reconverted into the sugar by Fischer and Hirschberger's method. On evaporating a solution of the pure sugar, it is obtained in microscopic needles of the composition $C_6H_{12}O_5$; it is very readily soluble, has a sweet taste, and is levorotatory, the rotatory power being $-112°$ immediately after solution, but gradually diminishing to $-77°$. On distillation with hydrochloric acid, it gives methylfurfuraldehyde; it reduces alkaline copper solutions, and shows the general reactions of the sugars. The *osazone* melts at about 159°. F. S. K.

Trimethylenimine, and a New Synthesis of β-Picoline. By A. LADENBURG and J. SIEBER (*Ber.*, **23**, 2727—2731).—Trimethylenediamine hydrochloride was subjected to dry distillation, the distillate treated with dilute hydrochloric acid, and the solution filtered and evaporated, so that a large quantity of ammonium chloride separated out. The residue was distilled with concentrated aqueous soda, and the distillate separated by fractionation into three portions, boiling respectively at 66—70°, 140—143°, and 148—151°. From the first fraction, trimethylenimine was separated as the bismuthoiodide, $(C_3H_7N,HI)_3,2BiI_3$, by the addition of a dilute solution of bismuth and potassium iodides. This salt is red; when distilled with soda, it yields the free base which boils at 66—70°, smells like piperidine, is very hygroscopic, and mixes with water and alcohol. The *platinochloride*, $(C_3H_7N)_2,H_2PtCl_6$, forms yellow needles melting at 196°. The second fraction was shown to contain β-picoline identical with that obtained from glycerine, whilst the third fraction consisted of β′-picoline, identical with that obtained from strychnine, and which Ladenburg has shown (this vol., p. 1432) to be different from the β-picoline mentioned above. These substances were identified by means of the melting points of their platino and mercuro-chlorides, and of the nicotinic acid which they yielded when oxidised.

C. F. B.

Methylnonylphenylhydrazone. By S. GRIMALDI (*Gazzetta*, **20**, 96—98).—*Methylnonylphenylhydrazone*, $C_9H_{19}\cdot CMe\colon N_2HPh$, prepared by heating methyl nonyl ketone (from oil of rue) with phenylhydrazine, is a heavy, neutral, orange-yellow oil with an aromatic odour which remains liquid at − 5°; sp. gr. = 0·94475 at 0°. It is insoluble in water, but dissolves in ether, carbon bisulphide, chloroform, &c. It is resinified by exposure to the air. It differs from both its constituents in having no reducing action on Fehling's solution even when heated with it.

S. B. A. A.

Derivatives of Acetylacetone. By A. COMBES (*Compt. rend.*, **111**, 272—274).—When well-cooled acetylacetone is gradually mixed with an equal molecular proportion of sulphuryl chloride, large quantities of hydrogen chloride and sulphurous anhydride are evolved, and a pungent colourless liquid is obtained which, on fractionation under ordinary pressure, boils at 156—158°. It consists of monochloracetylacetone mixed with a small quantity of the dichloro-derivative. The liquid is agitated with a concentrated solution of cupric acetate, and the compound $(C_5H_6O_2Cl)_2Cu$ separates in pale-green, silky, slender needles, which are washed with alcohol. When this compound is dissolved in dilute sulphuric acid, the solution extracted with ether, and the ether evaporated, monochloracetylacetone is obtained as a colourless, highly refractive liquid which boils at 156°, and is insoluble in water.

The monochloracetylacetone thus prepared has the constitution $CHClAc_2$, and when treated with sulphuryl chloride, yields the dichlorinated derivative CCl_2Ac_2, which boils at 87° under a pressure of 18—20 mm., and yields no metallic derivatives. C. H. B.

Formation of Glycocine from Chloracetic Acid. By K. KRAUT (*Ber.*, **23**, 2577).—It is advantageous, in preparing glycocine from chloracetic acid, to employ a very large excess of ammonium hydrate; the yield is then about 50 per cent. of the theoretical. F. S. K.

Alkyl Dicyanacetates. By A. HALLER (*Compt. rend.*, **111**, 53—56).—*Ethyl dicyanacetate*, $CHCy_2 \cdot COOEt$, is obtained by adding 22 grams of ethyl cyanacetate to a solution of 4·6 grams of sodium in 100 grams of absolute alcohol, and saturating the mixture with cyanogen chloride. It combines with a small quantity of ether, and is then soluble in water and alcohol, but insoluble in ether, but if dried over anhydrous sodium sulphate and placed in a desiccator, it loses ether, and is partially converted into a gelatinous, opaque mass insoluble in water and ether, but soluble in warm alcohol. It cannot be distilled without decomposition even in a vacuum. Its aqueous solution is strongly acid and decomposes when heated, evolving carbonic anhydride and hydrogen cyanide; with silver salts, it gives a white precipitate soluble in boiling water.

Ethyl dicyanacetate is a very energetic acid, and forms salts of the type $CMCy_2 \cdot COOEt$. The sodium salt crystallises from water in slender needles, and from alcohol in large crystals, very soluble in water or alcohol; its solutions give no precipitate with ferric salts, but there is a slight red coloration which is not removed by ether. The silver salt is white and insoluble in cold water or alcohol, but dissolves in boiling water or alcohol, from which it separates in microscopic prisms. The cupric salt forms a reddish-yellow precipitate which contains 3 mols. H_2O, and is insoluble in cold water.

Methyl dicyanacetate is obtained in the same way as the ethyl compound, but its formation is always accompanied by the production of a compound, $C_6H_8N_2O_3$, insoluble in cold water, alcohol, or ether, but soluble in boiling water or alcohol, from which it crystallises in white, lozenge-shaped plates.

Methyl dicyanacetate is also a strong acid. Its sodium salt crystallises from water or alcohol in slender needles or transparent prisms, which become opaque in a dry atmosphere; a solution of the salt gives a brownish-yellow, crystalline precipitate with cupric salts. The silver salt is white, and crystallises from boiling water in microscopic prisms.

These results confirm the author's conclusion (Abstr., 1882, 1189) that the introduction of cyanogen into a CH_2 group which is already united to two other negative radicles results in the production of an acid function. The alkyl dicyanacetates may be regarded as alkyl cyanomalonates in which a group COOR has been displaced by CN.

C. H. B.

New Acid of the Acetic Series. By E. GÉRARD (*Compt. rend.*, **111**, 305—307).—The seeds of *Datura stramonium* are extracted with ether, the ether distilled off, and the residue purified by solution in light petroleum, filtration, and distillation. A greenish-yellow oil is thus obtained in quantity amounting to about 25 per cent. of the weight of the seeds. It is saponified by lead oxide, and the dried lead salts are treated with ether to remove lead oleate and linoleate, which are present in considerable quantity. The residue is decomposed by hydrochloric acid, and the mixture of acids is dissolved in alcohol of 85°, the crystals which separate being purified by recrystallisation. Finally, the solution of the acid is fractionally precipitated by barium hydroxide, and the acid separated from the barium salt by treatment with hydrochloric acid, and purified by crystallisation from alcohol. It forms slender needles which melt at 55°, is somewhat soluble in cold alcohol, very soluble in boiling alcohol, ether, and light petroleum. It has the composition $C_{17}H_{34}O_2$, and is intermediate between palmitic and stearic acids, which it closely resembles, but its melting point is much lower. The author proposes to call it *daturic acid*. It is monobasic; the barium salt is anhydrous and insoluble in water, but crystallises from alcohol in microscopic needles; the zinc salt is very similar; the magnesium salt is also similar, but is much more soluble in hot alcohol. The ethyl salt, obtained in the same way as ethyl stearate, crystallises from strong alcohol in slender needles which melt at 27° and at 25° solidify in large lamellæ. C. H. B.

Addition of Chlorine and of Halogen Acids to Oleïc Acid and Elaïdic Acid. By S. Piotrowski (*Ber.*, **23**, 2531—2533).—*Dichlorostearic acid*, $C_{18}H_{34}O_2Cl_2$ is obtained when the theoretical quantity of chlorine is passed into a chloroform solution of elaïdic acid; it crystallises from alcohol in nacreous plates, melts at 32°, and is very readily soluble in all ordinary solvents except water. The *calcium* salt $(C_{18}H_{33}O_2Cl_2)_2Ca$ crystallises from hot absolute alcohol in needles, and is soluble in cold ether, but insoluble in cold alcohol; the *barium* salt has the same properties. The *methyl* salt, $C_{18}H_{33}Cl_2O_2Me$, crystallises in needles.

Chlorostearic acid, $C_{18}H_{35}O_2Cl$, can be prepared by saturating a glacial acetic acid solution of oleïc or elaïdic acid with hydrogen chloride at 0°, and keeping the solution for three to four days at the ordinary temperature. It crystallises from hot alcohol in slender needles, melts at 38°, and is readily soluble in most ordinary solvents except water. The *barium* salt is soluble in ether, but is precipitated from the solution on the addition of cold alcohol; the *calcium* salt shows a like behaviour.

Bromostearic acid, $C_{18}H_{35}O_2Br$, prepared in like manner from oleic or elaïdic acid, melts at 41°, and resembles the corresponding chlorine derivative in its behaviour with solvents. F. S. K.

Lithium Malonates. By G. Massol (*Compt. rend.*, **111**, 233—234).—Heats of formation: $C_3H_4O_4$ + LiOH develops +12·66 Cal., $C_3H_3O_4Li$ + LiOH develops +12·87 Cal., $C_3H_4O_4$ + 2LiOH develops +25·53 Cal.

Lithium hydrogen malonate forms anhydrous, colourless, crystalline crusts readily soluble in water; heat of dissolution, −1·43 Cal.

Lithium malonate forms hard, white, anhydrous, crystalline masses; heat of dissolution, +3·54 Cal. The heat of formation of the solid salt from solid acid and base is +33·56 Cal. The following table gives the heats of formation of the solid alkaline malonates:—

	Potassium.	Sodium.	Ammonium.	Lithium.
Hydrogen salt .	+27·87 Cal.	25·86 Cal.	22·78 Cal.	17·63 Cal.
Normal salt....	+48·56 „	41·50 „	41·00 „	33·56 „

C. H. B.

Silver Malonate. By G. Massol (*Compt. rend.*, **111**, 234—235).—Silver malonate, obtained by double decomposition, is an anhydrous, slightly yellowish-white, crystalline powder consisting of slender, microscopic needles in stellate groups. It blackens when exposed to light, and when heated, burns with vivid deflagration, leaving a residue of metallic silver. It is only slightly soluble in water; heat of dissolution at 20°, −9·8 Cal. The heat of formation of the precipitated salt from dissolved silver nitrate and potassium malonate is +9·83 Cal., from the dissolved acid and precipitated silver oxide, +18·84 Cal. These numbers are lower than the corresponding values for silver oxalate. C. H. B.

Conversion of Maleïc Acid into Fumaric Acid. By Z. H. Skraup (*Monatsh.*, **11**, 323—325).—Other acids besides the halogen acids and nitric can convert maleic into fumaric acid; their action is proportional to their acid-strength. The electrical conductivity has a distinct influence, though not in any simple proportion, on the rate of change; in this respect, strong hydrochloric, nitric, and sulphuric acids act unequally. The presence of lithium and ammonium chlorides accelerates the action of hydrochloric acid.

Parabromobenzyl maleate is not changed when heated for some hours at 200°, or with alcohol at 150°, unless the latter contains iodine or acetic acid. Silver maleate and parabromobenzyl bromide yield parabromobenzyl maleate (m. p. 80°) only, when heated in ether at its boiling point; but at 150°, a small quantity of parabromobenzyl fumarate (m. p 115°) is also formed.

In absence of water, parabromobenzyl maleate is changed into fumarate at the ordinary temperature by hydrochloric acid, and at higher temperatures by nitric acid and sulphuric acid, the last acting less readily than nitric acid.

It is pointed out that malic acid may be an intermediate product in the change of maleic into fumaric acid. The subject is being further investigated. A. G. B.

Symmetrical Trimethylenetricarboxylic Acid. By E. Buchner and H. Witter (*Ber.*, **23**, 2583—2585).—The further investigation of the acid (m. p. 220°) which is obtained from the additive product of ethyl fumarate and ethyl diazoacetate (compare Abstr., 1888, 1274) has shown that it is, as was supposed, symmetrical trimethylenetricarboxylic acid. It is not reduced by sodium amalgam even on boiling, and it is unchanged by concentrated hydrobromic acid, both in the cold and at 100°; as cis-1 : 2-trimethylenedicarboxylic acid, prepared by Conrad and Guthzeit's method, is also unchanged by concentrated hydrobromic acid at the ordinary temperature, the readiness with which 1 : 1-trimethylenedicarboxylic acid is decomposed by hydrobromic acid cannot be looked on as a general property of polycarboxy-derivatives of trimethylene.

The acid described as propargylenetetracarboxylic acid by Schacherl (Abstr., 1885, 1125) is 1 : 1 : 2 : 3-trimethylenetetracarboxylic acid. *Methyl trimethylenetetracarboxylate*, $C_3H_2(COOMe)_4$, is obtained when methyl bromofumarate is treated with ethyl sodiomalonate; it separates from ether in compact crystals, melts at 85°, boils at 205—215° under a pressure of 15 mm., and on hydrolysis it gives Schacherl's propargylenetetracarboxylic acid. The last-named compound is not acted on by potassium permanganate in alkaline solution, and when heated quickly to 196—198°, it is converted into trimethylenetricarboxylic acid (m. p. 220°) with evolution of carbonic anhydride.

F. S. K.

Acids of the Sugar Group. By E. Fischer (*Ber.*, **23**, 2625—2628).—d-Glucolactone is obtained in crystals when an aqueous solution of pure gluconic acid, prepared by decomposing the calcium salt with oxalic acid, is evaporated to a syrup, and then kept over sulphuric acid for 8—14 days; it can be purified by repeated recrystallisation from warm water, but it still shows a slight acid reaction. It melts at about 130—135°, has a sweet taste, and is very readily soluble in hot alcohol; its specific rotatory power is $[\alpha]_D = 68 \cdot 2$, but in the course of 24 hours the rotatory power gradually diminishes owing to partial conversion into the acid.

Gluconic acid seems to be very feebly levo-rotatory, but the solution quickly becomes dextro-rotatory, owing probably to the formation of lactone; a like behaviour is also exhibited by d-mannonic acid, as has been previously shown. On the other hand, the rotatory power of solutions of many lactones of this group gradually changes as they are partially converted into the acids, and it would seem that the so-called bi-rotation of the saccharoses is due to a similar cause; in aqueous solution, they are gradually converted into hydrated compounds which possess a rotatory power different from that of the anhydrous compound. All observations seem to show that anhydrous grape-sugar, for example, dissolves in water as the compound $C_6H_{12}O_6$, which is then gradually transformed into the heptahydric alcohol, $C_6H_{14}O_7$, the rotatory power becoming constant only when the change is complete.

Calcium l-mannonate, $(C_6H_{11}O_7)_2Ca + 3H_2O$, can be obtained in crystals by boiling an aqueous solution of pure l-mannolactone for half-an-hour with pure calcium carbonate, evaporating the filtered solution to a small volume, and adding alcohol to the hot solution in such quantities that it remains clear; the syrupy calcium salt which separates on cooling slowly solidifies when rubbed with a glass rod, and a crystal, introduced into a concentrated aqueous solution of the salt, causes the crystallisation of the whole. It forms slender needles, loses its water at 100°, and is readily soluble in warm, but only moderately easily in cold, water.

Arabonic acid phenylhydrazide, $C_5H_9O_5 \cdot N_2H_2Ph$, is precipitated in yellowish crystals when a moderately concentrated solution of the acid, lactone, or calcium salt is heated with phenylhydrazine and 50 per cent. acetic acid for 1½ hours at 100°. It crystallises from hot water in colourless plates, and melts at 215° with decomposition when quickly heated.

Xylosecarboxylic acid can be prepared by treating xylose with hydrocyanic acid in the usual manner. The basic *barium* salt crystallises from hot water, is very sparingly soluble in cold water, and has the composition $C_6H_{11}O_7Ba\cdot OH$; on decomposing the barium salt with the theoretical quantity of sulphuric acid and evaporating the solution, there remains a colourless syrup which consists of a mixture of acid and lactone. By reducing this mixture with sodium amalgam, a sugar is formed, the osazone of which is moderately easily soluble in hot water, and differs from all known hexosazones. F. S. K.

Hydroxygluconic Acid. By L. Boutroux (*Compt. rend.*, **111**, 185—187).—The author considers that the acid resembling glycuronic acid obtained by E. Fischer by the reduction of saccharic acid (this vol., p. 599) is probably identical with the hydroxygluconic acid which he obtained (Abstr., 1886, 682) by the action of a bacterium on glucose.

Hydroxygluconic acid, $C_6H_{10}O_7$, is lævogyrate, its rotatory power in a 2 per cent. solution being $[\alpha]_D = -14\cdot5°$. Its lead salt forms small, yellowish-white, irregular crystals which are only slightly soluble in water. Lead acetate, however, does not always precipitate solutions of hydroxygluconates, because the lead salt has a great tendency to remain in supersaturation. Hydroxygluconic acid resembles glycuronic acid in many respects, although the former is lævogyrate and very soluble in alcohol, whilst the latter is dextrogyrate and insoluble in alcohol. C. H. B.

Conversion of Thiocarbamide into Carbamide. By R. Maly (*Monatsh.*, **11**, 277—281).—This conversion has not been directly effected hitherto. The author finds that the sulphur in thiocarbamide is directly oxidised to sulphuric acid by potassium permanganate in neutral solution, according to the equation $CH_4N_2S + O_4 = CH_4N_2O + SO_3$; the quantity of oxygen actually used falls a little short of four atoms, but this is to be accounted for by the fact that a small quantity of the sulphur makes its appearance as potassium thiosulphate.

In acid solution, the above reaction does not take place, a new base being formed under these circumstances. A. G. B.

Ammoniacal Fermentation of Uric Acid. By F. Sestini and L. Sestini (*Landw. Versuchs-Stat.*, **38**, 157—164).—Uric acid, suspended in water, may be kept for more than a year without undergoing any change, but the addition of a very small amount of decomposed urine causes it to decompose quickly and completely in hot weather. Pure uric acid (4 or 6 grams) was put into a large flask with distilled water (4 or 6 litres) and urine (1 or 2 c.c.) added. By means of a suction pump, 2 litres of air was made to pass through the liquid four or five times a day. In another experiment, a stoppered flask was employed; this was frequently shaken and opened In a few days the liquid became alkaline from the formation of ammonium carbonate, and the amount of suspended uric acid diminished until, in seven or eight days, it disappeared entirely. In 12 or 13 days, the whole of the uric acid was changed into ammonium carbonate. The reaction is expressed thus: $C_5H_4N_4O_3 + 8H_2O + 3O = 4NH_4HCO_3 + CO_2$. In another experiment, made at a temperature of 20°, the uric acid was almost all decomposed in 20 days, when the experiment was stopped. It was found that only a little more than half the total nitrogen was present as ammonia, the rest being in organic compounds.

In a third experiment, with a temperature of 22—28°, nearly all the uric acid disappeared within seven days. On the eighth day, a part of the liquid was taken out, filtered, and distilled. The result showed that about $\frac{12}{17}$ of the uric acid was converted into ammonium carbonate and the rest into carbamide. Another portion of the liquid. not filtered, was kept for eight days longer, when it was found that the whole of the uric acid was converted into ammonia. It is possible that further investigation may show that other compounds besides carbamide (alloxan, for instance) are formed as intermediate products.

N. H. J. M.

Presence of Furfuraldehyde in Commercial Alcohols. By L. Lindet (*Compt. rend.*, 111, 236—237).—The author has applied the aniline acetate test to a large number of commercial alcohols, and finds that, contrary to the usual statement, furfuraldehyde is not a constant constituent. If the alcohol has been distilled over a naked fire, or if it is derived from grain which has been in contact with acids, then it contains furfuraldehyde; but if distilled with steam, and the grain has not been in contact with acids, the alcohol is free from furfuraldehyde.

The following quantities of furfuraldehyde per litre of alcohol were found in various brandies: cognac, 0·2 c.c.; cider, 0·03 c.c.; cherry, 0·02 to 0·13 c.c.; marc, 0·1 to 0·4 c.c.; and it is doubtless produced by the partial destructive distillation of the vegetable matter held in suspension in the liquids.

Alcohol from sugar, obtained by the action of mineral acids, contains 0·06—0·1 c.c. of the aldehyde per litre, even when distilled with steam; before fermentation, in fact, the aldehyde can be detected in the wort. Pure maize starch, saccharified by acids, yields, however, only traces of furfuraldehyde. Worts fermented by diastase contain only very small quantities of the aldehyde, and its formation is probably due to the action of lactic acid. In the case of beer, the wort remains neutral, and no furfuraldehyde can be detected. Molasses brandy contains 0·04 to 0·05 c.c. of the aldehyde per litre of alcohol, not formed, as direct experiments show, by the action of acids on canesugar, but due to the addition, in place of yeast, of worts in full fermentation, these worts having been prepared from grain which has been in contact with acids.

Alcohol from beet, artichokes, and potatoes, fermented in absence of acids, and distilled by steam, contains no furfuraldehyde.

C. H. B.

Preparation of Thiophen. By L. H. Friedburg (*Chem. Centr.*, 1890, ii, 8; from *J. Amer. Chem. Soc.*, 12, 83—90).—By heating a mixture of sodium succinate and phosphorus trisulphide, the author has obtained as much as 50 per cent. of the theoretical quantity of thiophen. He recommends that not more than 155 grams of sodium succinate, with twice the weight of phosphorus trisulphide, shall be employed in one operation. J. W. L.

Alteration of Compounds of the Benzene Series when Exposed to Air and Light. By A. BIDET (*Compt. rend.*, **111**, 47; compare Abstr., 1889, 595).—Many compounds, including aniline chloride, sulphate, and nitrate, toluidine, resorcinol, benzoic chloride, benzaldehyde, nitrocinnamic acids, naphthol, naphthylamine, and quinoline and its salts, were carefully purified, and remained quite colourless even after exposure to air and light for several months. The purest obtainable commercial samples of the same compounds became decidedly coloured when exposed under the same conditions, though they remained colourless if kept in the dark. From these results and his previous observations (*loc. cit.*), the author concludes that the property of becoming coloured when exposed to air and light is not inherent in pure organic compounds, but is due to the presence of impurities, the proportion of which, in some cases, may be very small indeed. C. H. B.

Action of Nitrous Anhydride on Various Substances in Solution in Carbon Bisulphide. By L. H. FRIEDBURG and J. A. MANDEL (*Chem. Centr.*, 1890, ii, 8—9; from *J. Amer. Chem. Soc.*, 12, 7—12).—The nitrous anhydride, prepared by heating arsenious anhydride with nitric acid, was purified by passing it over lead and collected in a cooled receiver. It was afterwards mixed with carbon bisulphide and added drop by drop to the several substances, also dissolved in carbon bisulphide. With benzene, mononitro- and para-dinitro-benzene are formed; with phenol, ortho- and para-nitrophenols and nitrosophenols are formed; with diphenylamine, para-nitro-diphenylamine and ortho- and para-dinitro-diphenylamine are formed, together with undefined nitroso-compounds. Attempts to introduce sulphur into the diphenyl molecule at the same time, by dissolving it in the carbon bisulphide, were unsuccessful. With diphenyl, nitrous anhydride reacts, with formation of paranitrodiphenyl, and another substance not yet investigated. Nitrous anhydride does not react with benzonitrile under ordinary pressures; it oxidises benzaldehyde to benzoic acid. With benzoic acid, it forms *nitrosobenzoic acid*, melting at 114°. Its barium salt, $(C_6H_4NO\cdot COO)_2Ba$, crystallises with 2 mols. H_2O. J. W. L.

Artificial Musk. By A. BAUR (*Compt. rend.*, **111**, 238—240).—Metaisobutyltoluene is heated on a water-bath for 24 hours with five times its weight of a mixture of sulphuric acid and fuming nitric acid. The product is subjected to a repetition of the same treatment, and is thus completely converted into trinitrobutyltoluene, which crystallises from alcohol in white needles melting at 96—97°, and insoluble in water, but soluble in alcohol, ether, and the usual solvents. Even in very dilute solutions this compound has a strong odour of musk, and for many purposes may replace the natural product. The latter, however, is quite different in composition; it is a non-nitrogenous resin. Trinitrobutyltoluene has no poisonous effects. It combines with naphthalene (in the proportion of 2 mols of trinitrobutyltoluene to 1 of naphthalene), forming a compound which crystallises from alcohol in large, white lamellæ melting at 89—90°; when distilled with water, naphthalene passes over, and the trinitro-derivative remains in the retort.

The homologues of isobutyltoluene behave in a similar manner Trinitroisobutylmetaxylene, which forms white needles melting at 110°, has an odour which cannot be distinguished from that of trinitroisobutyltoluene. C. H. B.

Action of Iodide of Nitrogen on some Organic Compounds. By R. Lepetit (*Gazzetta*, 20, 104—108).—When moist iodide of nitrogen is agitated with a cold aqueous solution of phenol containing a few drops of caustic soda, a deep-blue solution and a greyish precipitate are formed, with copious evolution of ammonia. The solution contains a mixture of mono-, di-, and tri-iodophenols, the blue coloration being probably due to a small quantity of some azotised product. The precipitate, which is probably identical with Lautemann's triiodophenol, crystallises from dilute alcohol in colourless needles, melts at 155°, dissolves in caustic potash and soda forming blue solutions, and is decomposed by concentrated nitric and sulphuric acids with separation of iodine.

α- and β-naphthol are differently affected by iodide of nitrogen: on adding an alkaline solution of β-naphthol to the strongly cooled iodide, a brownish-green precipitate is formed, which redissolves after standing for some time. From the solution, a current of sulphurous anhydride precipitates a moniodonaphthol which melts at 94·5°, and is otherwise identical with Meldola's orthiodonaphthol. When iodide of nitrogen is added to β-naphthol, only a slight deposit of dinaphthol is formed.

On adding a solution of α-naphthol in caustic soda to moist iodide of nitrogen, or *vice versâ*, a light, violet-black precipitate is formed which greatly resembles the iodide in appearance, but does not evolve iodine on heating or on treatment with strong acids. It is insoluble in alcohol, acetic acid, ether, chloroform, alkalis, and acids, but dissolves in aniline; on heating, it partially fuses and decomposes, leaving a carbonaceous residue.

With iodide of nitrogen, salicylic acid forms a reddish, amorphous, unstable compound which decomposes with separation of iodine. Acetone yields iodoform and a substance having the pungent odour of an iodacetone. With ethyl acetoacetate, a yellowish oil is obtained; diazobenzene chloride is decomposed on addition of iodide of nitrogen into benzene and resinous products. S. B. A. A.

Reduction Products of Iodophenols. By J. Messinger and N. Pickersgill (*Ber.*, 23, 2761—2764).—Iodothymol is dissolved in ether, alcoholic potash added, and then zinc-dust in successive small quantities, the mixture being finally boiled for two days in a reflux apparatus. The alcohol is evaporated as far as possible, water being continually added, and then, on the addition of dilute sulphuric acid, a substance is precipitated which, after careful purification, crystallises from dilute acetic acid or alcohol in small, white needles melting at 160°. It is *dithymol*,

$$OH{\cdot}C_6H_2MePr^{\alpha}{\cdot}C_6H_2MePr^{\alpha}{\cdot}OH + 2H_2O,$$

probably [$Me : OH : Pr^{\alpha} : C_{10}H_{13}O = 1 : 3 : 4 : 6$], since it gives no nitroso-derivative with nitrous acid, as compounds usually do in which the hydrogen that stands in the para-position to the hydroxyl is not replaced. The *benzoyl* derivative, prepared from dithymol and benzoic chloride, crystallises from benzene in thick, white tables which melt at 209—210°, and dissolve easily in benzene and chloroform, sparingly in alcohol, ether, and light petroleum. The *acetyl* derivative, prepared from dithymol and acetic anhydride, crystallises from alcohol in needles which melt at 113—114°, and dissolve easily in alcohol, ether, benzene, light petroleum, and chloroform.

C. F. B.

Action of Hydroxylamine on Nitrosophenols. By F. KEHRMANN and J. MESSINGER (*Ber.*, **23**, 2815—2820).—β-Naphthaquinonedioxime is prepared by the action of hydroxylamine (2—3 mols.) on nitroso-β-naphthol dissolved in excess of aqueous soda; the reaction proceeds in the cold, and the dihydroxime is precipitated on the addition of dilute sulphuric acid; it melts at 180—181°, and its preparation in this manner affords a ready means of obtaining 1 : 2-naphthylenediamine.

Diquinoyltetroxime is formed in a similar manner from dinitrosoresorcinol. On treating with 5 parts of nitric acid of sp. gr. 1·45, diluting with ice water, and adding potassium carbonate, a potassium salt is deposited which crystallises from water in brownish-yellow needles, and is being further investigated. A corresponding compound is obtained from toluenetetroxime, prepared from dinitroso-orcinol and hydroxylamine. Attempts to obtain benzene hexoxime were unsuccessful.

On treating paranitrosophenol with hydroxylamine as above, and extracting the acid solution with ether, white crystals are obtained which quickly decompose, with the formation of phenol and a considerable quantity of resinous matter. Nitrosothymol behaves in a similar manner; on dissolving the white compound in aqueous soda and adding an equal weight of some phenol, such as cresol, thymol, phenol, or α-naphthol, but not β-naphthol, an intense blue colour is produced, which turns red on the addition of an acid, and, after some time, becomes colourless. The blue compound could not be obtained in crystals. Bromonitrothymol behaves in a similar manner. The above reactions may be explained by assuming that paraquinoneoxime reacts with hydroxylamine as if it were a trinitrosophenol, and yields diazophenol; by the further action of hydroxylamine, hydrogen diazophenol, $OH{\cdot}C_6H_4{\cdot}NH{\cdot}NH{\cdot}OH$ (the white compound), is formed, and this then decomposes into phenol, nitrogen, and water.

J. B. T.

Desmotropy in Phenols. By J. HERZIG and S. ZEISEL (*Monatsh.*, 291—310, 311—322; compare Abstr., 1888, 822; 1889, 247, 966).—For the ethylation of resorcinol, the latter (100 grams) is dissolved in absolute alcohol (1 litre), potassium hydroxide (204 grams) is added, and the mixture is warmed until everything has dissolved; ethyl iodide (567 grams) is then slowly added, and the warming continued until the liquid is neutral, when more potassium hydroxide and ethyl iodide are added, and the heating continued until the liquid is once more neutral. The alcohol is now distilled off, and the oil precipitated with water and shaken with ether; the ethereal solution is washed successively with alcoholic potash and water, and distilled. The dried residue amounted to 154 per cent. of the resorcinol; it was first fractionally distilled at 40 mm. pressure.

The first two fractions boiled, under the ordinary pressure, at 228—232°, and consisted largely of resorcinol diethyl ether; the other portion was not investigated. Resorcinol diethyl ether, $C_6H_4(OEt)_2$, crystallises in transparent, colourless prisms which melt at 12·4°; it boils, at 0° and 756 mm., at 234·4—235·2° (corr.; Barth, 235—236°; Pukall, 228—230°); it has a characteristic odour, and gives a green colour with acetic acid and potassium nitrite.

Two isomeric bromo-derivatives are obtained by brominating resorcinol diethyl ether in glacial acetic acid (20 parts), precipitating with water, and crystallising from alcohol; they are separated by carefully adding water to their solution in acetic acid, as long as the crystals that separate vary in melting point. In this way, *α-dibromoresorcinol diethyl ether* is obtained first; it crystallises in long, slender, colourless prisms which melt at 100—101°. *β-Dibromoresorcinol diethyl ether* crystallises in colourless needles, and melts at 75—77°.

The remaining fractions were again fractionated at 19 mm.; the two chief products thus obtained boiled at 146—151° and 160—165° respectively. The former of these is a dark resin, insoluble in water, but soluble in alkalis to a red liquid with a green fluorescence; its analysis gives numbers which agree, as far as carbon and hydrogen are concerned, with ethylresorcinol diethyl ether, $C_6H_3Et(OEt)_2$, but the numbers for ethoxyl do not agree with this formula. It is probable that other triethyl-derivatives of resorcinol are also present.

The fraction boiling at 160—165° consists of *secondary-tertiary-triethylresorcinol ethyl ether*, $C_6H_2Et_3O{\cdot}OEt$; it forms a thick, yellow oil with a somewhat spicy odour; it dissolves in strong sulphuric acid with an intense yellow colour, and is precipitated unchanged by water. It is soluble in most organic solvents.

Secondary-tertiary-triethylresorcinol, $C_6H_2Et_3O{\cdot}OH$, is obtained (9 per cent.) when the above ethyl ether is heated with 20 per cent. hydrochloric acid in a reflux apparatus for two hours; the reaction product is shaken with dilute potash solution, and the solution acidified and shaken with ether. When recrystallised from alcohol, it forms white needles, melts at 183—185°, and is soluble in alcohol, light petroleum, and ether. The *acetyl derivative*, $C_6H_2Et_3O{\cdot}OAc$, forms monosymmetric crystals ($a : b : c = 0{\cdot}7089 : 1 : 1{\cdot}0243$; $\beta = 65° 16' 24''$) melting at 63—65°.

The authors doubt the existence of De Luynes' and Lionet's "triethylorcinol" (*Compt. rend.*, 65, 213). Pelizzari has privately informed them of the results of a research in which he has obtained a substance agreeing in analysis with the formula $C_7H_3Et_2O\cdot OEt$, and thus apparently established De Luyne's and Lionet's compound; the authors, however, have failed to obtain it.

The ethylation of orcinol is conducted similarly to that of resorcinol (see above). The product was fractionally distilled at 20 mm. pressure, and the following definite compounds have been isolated:—

Orcinol diethyl ether, $C_7H_6(OEt)_2$, constitutes the fraction distilling at 144—150° (20 mm.), and is obtained pure by fractionally freezing the crude product until a portion melting at 16—16·5° is obtained. It crystallises in white needles, boils at 250·9—251·9° (corr., 0° and 745 mm.), and is insoluble in water, but dissolves in the usual organic solvents. *Dibromorcinol diethyl ether*, forms long, white needles; it melts at 142—144°, and dissolves sparingly in cold glacial acetic acid and cold alcohol, but more freely in hot alcohol.

The fraction boiling at 165—170° (20 mm.) is probably a mixture of $C_7H_4Et_3O\cdot OEt$ and $C_7H_4Et_2(OEt)_2$, but neither of them has been isolated from this fraction.

Secondary-tertiary-triethylorcinol ethyl ether, $C_7H_4Et_3O\cdot OEt$, constitutes the fraction which boils at 175—180°; its properties are not described in the paper.

Secondary-tertiary-triethylorcinol, $C_7H_4Et_3O\cdot OH$, is obtained when the above ethyl ether is heated with hydrochloric acid (sp. gr. 1·1) for three hours in a reflux apparatus. The product is dissolved in ether and the solution shaken with dilute potash; the potash solution is then acidified and shaken with ether, which dissolves the new compound. When recrystallised from alcohol, it forms colourless needles which melt at 142—144°, and are insoluble in water. The *acetyl derivative*, $C_7H_4Et_3O\cdot OAc$, forms colourless, monosymmetric crystals ($a : b : c = 0{\cdot}6369 : 1 : ?$; $\beta = 60° \, 8' \, 37''$) which melt at 71—73°. By saponifying the acetyl-derivative with sodium hydroxide, it is reconverted into the original triethylorcinol melting at 192—193°. [The authors apparently ignore the fact that they have already given the melting point as 142—144°.—ABSTRACTOR.]

A. G. B.

Orceïn. By K. ZULKOWSKI and K. PETERS (*Monatsh.*, 11, 227—245).—The authors have obtained three distinct colouring matters by the action of ammonia and air on orcinol, and find that the formulæ hitherto given for orcein are based upon analyses of impure products.

50 grams of crystallised orcinol are dissolved in water (200 c.c.), and ordinary ammonia solution (200 c.c.) is added. The mixture is put into a large flask and covered with a beaker. After some two months, the liquid becomes a thickish magma; this is transferred to a thick-walled flask, warmed on the water-bath, and the ammonia removed, as far as possible, by means of a water-pump. Hydrochloric acid is then added until the liquid is neutral, and the resulting precipitate, which contains all three colouring matters, is filtered, washed with water, and dried at as low a temperature as possible.

What colouring-matter remains in the filtrate is thrown out, after concentration, by sodium chloride, and dried. The mixed precipitates are washed with ether for eight days, to dissolve the yellow colouring-matter, and then with water to remove salt, and, finally, heated with strong alcohol for some time and filtered while hot, whereby the orceïn is dissolved and the third colouring-matter left undissolved. To obtain the orceïn, the alcoholic solution is evaporated, diluted with water, again heated, and allowed to cool slowly, when the orceïn crystallises; it is filtered off and dried in a vacuum.

Thus prepared, orceïn, $C_{28}H_{24}N_2O_7$, is a brown powder, and only shows a metallic lustre when dried in masses; under the microscope it is found to consist of very small, felted crystals. It is insoluble in water, ether, benzene, chloroform, and carbon bisulphide, but dissolves in acetone, glacial acetic acid, and alcohol; the solution is carmine, and becomes bluish-violet on addition of alkalis. Strong sulphuric acid dissolves orceïn in the cold to a bluish-violet solution, which is not precipitated, but is turned carmine by water.

To obtain the *yellow* colouring-matter, $C_{21}H_{19}NO_5$, the ethereal solution (see above) is distilled, and the residue (about 15 per cent. of the original orcinol) dissolved in hot alcohol and filtered; the filtrate is diluted with water, warmed until the precipitated colouring-matter has redissolved, and left to crystallise. When dry, it is a brown powder, which has a green metallic lustre, and consists of well formed, deep-yellow microscopic prisms; it is slightly soluble in hot water, freely so in ether and in alcohol, to an orange-yellow solution, which is changed to deep-violet by alkalis. Strong sulphuric acid dissolves it to a violet solution.

The third colouring-matter, left undissolved by the alcohol, is an amorphous powder, which is insoluble in all the usual solvents, and hence can not be purified for analysis. It has a green metallic lustre, and dissolves in ammonia and alkalis with a dark blue colour, which is turned onion-red when the solution is diluted and acidified; it separates from the acid solution, after a time, in cherry-red flocks. This substance is possibly identical with litmus, and is being further investigated.

No orceïn was obtained by the action of air on an alkaline solution of orcinol.

Orceïn can be more quickly prepared by acting on orcinol (100 parts) with ammonia (6 parts) and hydrogen dioxide (35 parts); the two bye-products described above are formed in this case also, and the separation is carried out in the same way.

A colouring-matter is obtained by acting on resorcinol with ammonia and hydrogen dioxide; it dissolves in alcohol to a dirty-red solution, but not in other solvents; it resembles the litmus-like substance described above, but has not been further investigated.

When a mixture of orcinol (142 parts) and resorcinol (110 parts) is acted on by hydrogen dioxide (3400 parts of 3 per cent. solution) in ammonia (7·7 parts of 22 per cent. solution) for some days, and the solution acidified, a precipitate is obtained which yields a magenta-red solution when digested with alcohol, and an insoluble colouring-matter (18 per cent.) similar in properties to litmus. The alcoholic solution contains a new colouring matter, *reso-orcein*, $C_{26}H_{20}N_2O_7$; this, by diluting with water and crystallising the solution, is obtained in fragments, having a lustre like bronze, and consisting of microscopic crystals. Reso-orcein differs from orcein in being more soluble in dilute alcohol, and in the solution having a bluer shade and becoming a pure blue when alkaline; moreover, it dissolves with a brilliant blue colour in strong sulphuric acid. Further experiments were tried to obtain colouring matters from mixtures of orcinol and higher phenols, but with indefinite results. The whole subject is still under investigation. A. G. B.

Tetramethylphloroglucinol. By A. Spitzer (*Monatsh.*, **11**, 287—290).—When tetramethylphloroglucinol (1 gram; this vol., p 1110), is heated with 40 per cent. hydrochloric acid (20 c.c.) in a sealed tube at 200° for seven hours, acetic, isobutyric, and carbonic acids, diisopropyl ketone, and, perhaps, methyl isopropyl ketone are obtained. A. G. B.

Reduction of Nitriles. By M. Freund and P. Immerwahr (*Ber.*, **23**, 2845—2858).—Diphenylacetonitrile is dissolved in alcohol and treated with 2·5 times the theoretical quantity of sodium, the product is distilled in a current of steam, the distillate neutralised with hydrochloric acid and extracted with ether; on evaporation, diphenylmethane is obtained. The aqueous solution is evaporated, and the residue recrystallised from alcohol; white needles are deposited on cooling, which melt at 255°, and consist of asymmetrical *β-diphenylethylamine hydrochloride*, $CHPh_2{\cdot}CH_2{\cdot}NH_2,HCl$. It may also be obtained in the form of rhombic plates. The *platinochloride* forms a pale yellow, crystalline powder. The *free base* is a colourless, viscid liquid.

Benzylfurfuryl, $C_4OH_3{\cdot}CH_2{\cdot}CH_2Ph$, is prepared in a similar manner by the reduction of α-phenylfurfuracrylonitrile, $C_4OH_3{\cdot}CH{:}CPh{\cdot}CN$; it is a colourless, oily liquid boiling at 241°, and is readily miscible with alcohol, ether, benzene, and carbon bisulphide; the yield is 30—40 per cent. of the nitrile employed. All attempts to prepare hydrogen, bromine, and nitro-derivatives were fruitless, nor could the furfuran ring be eliminated by the action of hydrochloric acid.

γ-Furfur-β-phenylpropylamine (β-furfurylphenylethylamine),

$$C_4OH_3{\cdot}CH_2{\cdot}CHPh{\cdot}CH_2{\cdot}NH_2.$$

is obtained, together with the previous compound, as a colourless, oily liquid boiling at 282—283°; it is miscible with alcohol and ether. The *hydrochloride* is prepared by adding concentrated hydrochloric acid to the free base; it is readily soluble in water, and melts at 176 The *platinochloride* forms a pale yellow, crystalline powder, which commences to decompose at 150°, and melts at 175°. The *aurochloride* crystallises in pale yellow, metallic, lustrous needles, which readily decompose. The *mercurochloride* crystallises in white needles melting at 175°. The *picrate* is a light yellow, crystalline powder melting at 152°. *γ-Furfur-β-phenylpropylcarbamide*,

$$C_4OH_3{\cdot}CH_2{\cdot}CHPh{\cdot}CH_2{\cdot}NH{\cdot}CO{\cdot}NH_2,$$

is prepared by the action of potassium cyanate on the amine, and is deposited from absolute alcohol in lustrous crystals which melt at 101°. The corresponding phenylthiocarbamide,

$$C_4OH_3·CH_2·CHPh·CH_2·NH·CS·NHPh,$$

is formed by the action of phenylthiocarbamide, and is obtained from alcohol in white crystals melting at 113°. *γ-Furfur-β-phenylpropyl alcohol*, $C_4OH_3·CH_2·CHPh·CH_2·OH$, is a colourless liquid, and is prepared by the action of silver nitrite on the amine hydrochloride.

α-Paranitrophenylfurfuracrylonitrile, $C_4OH_3·CH{:}C(CN)·C_6H_4·NO_2$, is formed by the action of a small quantity of sodium ethoxide on paranitrobenzyl cyanide and furfuraldehyde. It crystallises from alcohol in slender needles, and from benzene in nodular aggregates, melting at 171—173°. Attempts to reduce this compound were not very successful. On heating amidobenzyl cyanide and furfuraldehyde in molecular proportion, a compound with the formula $C_4OH_3·CH{:}N·C_6H_4·CH_2·CN$ is obtained, crystallising from alcohol in lustrous plates melting at 93—94°; on exposure to the air, it becomes red in colour. *α-Paramidophenylfurfuracrylonitrile*,

$$C_4OH_3·CH{:}C(CN)·C_6H_4·NH_2,$$

is prepared by the action of sodium ethoxide on furfuraldehyde and amidobenzyl cyanide; it crystallises from alcohol in needles melting at 111—112°. The *diacetyl derivative*, $C_4OH_3·CH{:}C(CN)·C_6H_4·NAc_2$, is obtained from diacetylamidobenzyl cyanide and furfuraldehyde in a similar manner, and is deposited from alcohol in pale yellow crystals which melt at 203—204°.

An *allylthiocarbamide*, with the formula

$$CN·CH_2·C_6H_4·NH·CS·NH·C_3H_5,$$

is formed by the action of allylthiocarbamide on amidobenzyl cyanide; on treating this compound with furfuraldehyde, an insoluble substance is obtained which melts at 206—208°, and has the formula

$$C_4OH_3·CH{:}C(CN)·C_6H_4·NH·CS·NH·C_3H_5.$$

Amidobenzylcyanophenylthiocarbamide melts at 140—141°; on treatment with furfuraldehyde, the compound

$$C_4OH_3·CH{:}C(CN)·C_6H_4·NH·CS·NHPh$$

is formed; it may be crystallised from alcohol, and melts at 159—160°.

α-Phenyl-β-cinnamenylacrylonitrile, $CHPh{:}CH·CH{:}CPh·CN$, is prepared by the action of sodium ethoxide on cinnamaldehyde and benzyl cyanide; it crystallises from alcohol in slender needles melting at 118—119°, and is insoluble in water. By the reduction of this compound, an amine is formed in very small quantity, but the chief product is *diphenylbutylene*, $CHPh{:}CH·CH_2·CH_2Ph$, which is deposited from alcohol in white crystals melting at 39°; it readily dissolves in ether and chloroform, but is insoluble in water. The *dibromide*, $CHPhBr·CHBr·CH_2·CH_2Ph$, is obtained by the action of bromine in the cold, and crystallises from alcohol in white needles melting at 83°. By the action of fuming nitric acid on the hydrocarbon, a compound is formed which melts at 191°, and is probably a *tetranitro-derivative*. *Diphenylbutane*, $CH_2Ph\cdot CH_2\cdot CH_2\cdot CH_2Ph$, is prepared by the reduction of the unsaturated compound with hydriodic acid and phosphorus at 250°; it is deposited from alcohol in white crystals which melt at 52°, and are insoluble in water, but readily dissolve in chloroform or ether. J. B. T.

Triphenylamine Derivatives. By R. HERZ (*Ber.*, 23, 2536—2542; compare Heydrich, Abstr., 1886, 1105).—*Nitrotriphenylamine*, $NPh_2\cdot C_6H_4\cdot NO_2$, is formed when finely divided triphenylamine is gradually treated with nitric acid of sp. gr. 1·48 in glacial acetic acid solution, first at the ordinary temperature, and then at 45—50°. It crystallises from dilute acetic acid in golden plates, melts at 139—140° with decomposition, and is readily soluble in warm benzene, ether, glacial acetic acid, &c., but only sparingly in water and cold dilute alcohol. It dissolves in concentrated sulphuric acid yielding a dark blue solution, and, on reduction with tin and hydrochloric acid, it is converted into amidotriphenylamine, the *hydrochloride* of which crystallises in colourless, sparingly soluble needles, and has the composition $C_{18}H_{16}N_2,HCl$.

Amidotriphenylamine is a colourless, crystalline compound, which rapidly oxidises, and becomes reddish-violet on exposure to the air; its *acetyl* derivative, $NPh_2\cdot C_6H_4\cdot NHAc$, crystallises from dilute acetic acid in long needles melting at 197°.

Dinitrotriphenylamine, $NPh(C_6H_4\cdot NO_2)_2$, is obtained by nitrating triphenylamine as described above, but at a slightly higher temperature (55—60°) It crystallises from dilute acetic acid in slender, yellow needles, melts at 206—207°, and is readily soluble in benzene and boiling glacial acetic acid, but only sparingly in ether and hot alcohol, and insoluble in water and cold alcohol; it dissolves in concentrated sulphuric acid with a bluish-violet coloration.

Diamidotriphenylamine, $NPh(C_6H_4\cdot NH_2)_2$, prepared by reducing the dinitro-compound with tin and hydrochloric acid, crystallises from very dilute alcohol in colourless needles, and melts at 187° with decomposition. The *hydrochloride*, $C_{18}H_{17}N_3,2HCl$, crystallises in colourless plates, and is readily soluble in water. The *diacetyl* derivative, $C_{22}H_{21}N_3O_2$, crystallises from dilute acetic acid in colourless plates, and melts at 268—269°.

The author could not obtain the saffranine reaction with triamidotriphenylamine hydrochloride and chloranil under the conditions described by Heydrich (*loc. cit.*); the mono-, di-, and tri-amido-derivatives of triphenylamine all give deep blue or violet induline-like colour reactions when treated with chloranil in glacial acetic acid solution under various conditions. When, however, a very small quantity (about 0·0005 gram) of triamidotriphenylamine hydrochloride is dissolved in concentrated sulphuric acid (5 c.c.) containing a trace of fuming nitric acid, a dark-green solution is produced, which becomes deep blue on warming: on the gradual addition of water to the well-cooled solution, the colour changes to magenta-red, and a beautiful, red fluorescence is observed.

A compound of the composition $NHPh_2,2C_6H_2Cl(NO_2)_3$ is deposited in deep red needles when diphenylamine (1 mol.) is warmed with picryl chloride (2 mols.) in toluene solution, and the solvent partially evaporated; it melts at 65—66° with partial decomposition, is readily soluble in all ordinary solvents except water, and is decomposed by boiling dilute potash.

Triphenylaminetrisulphonic acid can be obtained by heating finely-divided triphenylamine with fuming sulphuric acid for a short time at 60°; the *sodium* salt, $N(C_6H_4{\cdot}SO_3Na)_3$, separates from alcohol as a crystalline powder, and is very readily soluble in water.

Diphenylnaphthylamine, $C_{10}H_7{\cdot}NPh_2$, prepared by treating potassiodiphenylamine with α-bromonaphthalene in boiling aniline solution, crystallises from boiling dilute alcohol in colourless needles, melts at 142°, boils at 335—340° (80—85 mm.), and is very readily soluble in most ordinary warm solvents, but almost insoluble in cold dilute alcohol, and insoluble in water; it dissolves in concentrated sulphuric acid yielding a light-green solution, and on warming, a sulphonic acid is formed. F. S. K.

Dinitrodimethylamidodiphenylamine. By E. Lellmann and F. Mack (*Ber.*, **23**, 2739—2740).—If a concentrated aqueous solution of dinitrochlorobenzene $[Cl : (NO_2)_2 = 1 : 2 : 4]$ (1 mol.), paramidodimethylamine hydrochloride (1 mol.), and soda (3 mols.) is warmed on the water-bath, *dinitrodimethylamidodiphenylamine*,

$$NMe_2{\cdot}C_6H_4{\cdot}NH{\cdot}C_6H_3(NO_2)_2,$$

separates; it crystallises in bronze-coloured scales melting at 168°. The *hydrochloride*, $C_{14}H_{14}N_4O_4,HCl$, forms yellow crystals, which are decomposed by water. When it is reduced with hydrochloric acid and zinc-dust, a colourless solution is finally obtained, doubtless containing the compound $NMe_2{\cdot}C_6H_4{\cdot}NH{\cdot}C_6H_3(NH_2)_2$. If the neutral or slightly alkaline solution is allowed to remain in contact with air, a blue colouring matter separates out at the surface. C. F. B.

Xylylhydrazine. By A. Klauber (*Monatsh.*, **11**, 282—286).—*Sodium α-metaxylylhydrazinesulphonate* is prepared as follows:—50 grams of finely-powdered α-metaxylidine hydrochloride are suspended in a mixture of 200 grams of water and 40 grams of hydrochloric acid. The mixture is well cooled, and a concentrated solution of 25 grams of sodium nitrite is poured in; 250 grams of normal sodium sulphite is then added, and the whole well shaken, when it becomes at first red, and subsequently light yellow. The mixture is then warmed until the precipitate dissolves, and treated with zinc-dust and acetic acid until colourless, after which it is concentrated until the new salt crystallises. It forms colourless tables ($\frac{1}{2}$ mol. H_2O) which decompose at 250°, and are sparingly soluble in alcohol and water.

α-Metaxylylhydrazine, $C_8H_9N_2H_3$, is obtained as its *hydrochloride* when the above salt is decomposed by hydrochloric acid, and is prepared from this by adding an alkali; it crystallises in slender, pale-yellow needles which melt at 85°, and decompose when distilled, even in carbonic anhydride, with evolution of ammonia. It decomposes in air forming oily substances and ammonia. It is sparingly soluble in water, more freely in ether, and very freely in alcohol. It reduces Fehling's solution on warming. In behaviour it is analogous to phenylhydrazine. A. G. B.

Orthanisamine and Salicylamine. By H. GOLDSCHMIDT and H. W. ERNST (*Ber.*, **23**, 2740—2746).—*Orthanisaldoxime*,

$$OMe{\cdot}C_6H_4{\cdot}CH{:}NOH,$$

was obtained by warming orthanisaldehyde with a neutral solution of hydroxylamine. It crystallises from alcohol in long, white needles melting at 92°. *Carbanilido-orthanisaldoxime*,

$$OMe{\cdot}C_6H_4{\cdot}CH{:}NO{\cdot}CO{\cdot}NHPh,$$

is formed when equal molecular proportions of the oxime and phenyl cyanate are warmed together. It forms small, white needles melting at 105°, and is decomposed by alkalis.

Orthanisamine, $OMe{\cdot}C_6H_4{\cdot}CH_2{\cdot}NH_2$, is formed by reducing the oxime with sodium amalgam and acetic acid. It is a colourless liquid boiling at 224° under 724 mm. pressure. It dissolves in most solvents, and its aqueous solution is strongly alkaline. It readily absorbs carbonic anhydride from the air, solidifying to a white mass. The *hydrochloride*, $C_8H_{11}NO,HCl$, crystallises from alcohol in white prisms which melt at 150°, and are very soluble in water. The *platinochloride*, $(C_8H_{11}NO)_2,H_2PtCl_6 + 2H_2O$, crystallises from water in brilliant, golden-yellow plates melting at 187. *Orthanisylacetamide*, $OMe{\cdot}C_6H_4{\cdot}CH_2{\cdot}NHAc$, formed by the action of acetic acid on the amine, crystallises from alcohol in long, colourless needles which melt at 97°, and dissolve also in ether. *Orthanisylcarbamide*, $OMe{\cdot}C_6H_4{\cdot}CH_2{\cdot}NH{\cdot}CO{\cdot}NH_2$, formed by the action of potassium cyanate on the hydrochloride of the amine, crystallises from water in long, transparent needles melting at 127°. *Orthanisylphenylcarbamide*, $OMe{\cdot}C_6H_4{\cdot}CH_2{\cdot}NH{\cdot}CO{\cdot}NHPh$, formed by the action of phenyl cyanate on the amine, crystallises from alcohol in long, colourless needles which melt at 145°, and dissolve also in ether and benzene.

Salicylamine or *orthohydroxybenzylamine*, $OH{\cdot}C_6H_4{\cdot}CH_2{\cdot}NH_2$, was obtained by heating the hydrochloride of the amine for several hours with concentrated hydrochloric acid in sealed tubes at 150°. It crystallises from ether in groups of small needles which melt at 121°, have a smell resembling that of aldehyde-ammonia, dissolve in alkalis, and exhibit both basic and phenol-like properties. The *hydrochloride*, C_7H_9NO,HCl, crystallises from alcohol in colourless needles. The *platinochloride*, $(C_7H_9NO)_2,H_2PtCl_6 + 2H_2O$, crystallises from water in golden-yellow needles which melt with decomposition at 197°. *Orthohydroxybenzylacetamide*, $OH{\cdot}C_6H_4{\cdot}NHAc$, formed by the action of acetic anhydride on salicylamine, crystallises from ether in colourless needles melting at 140°. An attempt to prepare a diacetyl derivative was unsuccessful. *Orthohydroxybenzylcarbamide*, $OH{\cdot}C_6H_4{\cdot}CH_2{\cdot}NH{\cdot}CO{\cdot}NH_2$, obtained from salicylamine hydrochloride and potassium cyanate, crystallises from alcohol in colourless prisms melting at 170°, and soluble in hot water and alkalis. *Ortho-*

hydroxybenzylphenylcarbamide, $OH\cdot C_6H_4\cdot CH_2\cdot NH\cdot CO\cdot NHPh$, formed from salicylamine and phenyl cyanate, crystallises from alcohol in groups of small needles which melt at 155°, and dissolve also in ether, benzene, and alkalis. C. F. B.

Oximes. By H. Goldschmidt (*Ber.*, 23, 2746—2749).—*Paraditolylketoxime*, $C_6H_4Me\cdot C(NOH)\cdot C_6H_4Me$ [$CNOH : Me : Me = 1 : 4 : 4'$], was prepared by acting on paraditolyl ketone (obtained from paratoluic chloride, toluene, and aluminium chloride) with an alkaline solution of hydroxylamine. It crystallises from alcohol in brilliant, transparent prisms which melt at 163°. When heated with concentrated sulphuric acid, it is transformed into an isomeric substance which crystallises from alcohol in colourless needles melting at 160°, and differing from the ketoxime in its insolubility in alkalis. It was shown to be the paratoluidide of paratoluic acid,

$$C_6H_4Me\cdot CO\cdot NH\cdot C_6H_4Me\ [CO : Me = 1 : 4,\ NH : Me = 1 : 4],$$

because when it is heated at 200° with concentrated hydrochloric acid in a sealed tube, paratoluic acid and paratoluidine are formed. It follows then that in the transformation of a ketoxime into a substituted acid amide, the nitrogen atom takes the place in the benzene ring that was previously occupied by the carbon atom.

If equivalent quantities of phenyl cyanate and the benzyl derivative of isobenzaldoxime,  $O<\begin{array}{l}N\cdot CH_2Ph\\ \vert\\ CHPh\end{array}$, are dissolved in benzene and the solution boiled, benzylphenylcarbamide, $NHPh\cdot CO\cdot NH\cdot CH_2Ph$, seems to be formed. But if the reaction is allowed to take place at the ordinary temperature, a residue is obtained when the benzene is evaporated which crystallises from alcohol in white needles melting at 121, and having the composition $C_{14}H_{18}N_2O_2$, that is, an additive compound of the cyanate and the oxime derivative. But it is not decomposed by boiling with acids or alkalis, and only when heated with concentrated hydrochloric acid in a sealed tube at 100° is it split up, yielding carbonic anhydride together with benzaldehyde and aniline hydrochloride, the last two substances crystallising together. The constitution of this substance is as yet undetermined.

C. F. B.

Two Different Modifications of Paranitrobenzylisobenzaldoxime. By R. Behrend and E. König (*Ber.*, 23, 2750—2752).—When β-benzylparanitrobenzylhydroxylamine,

$$NO_2\cdot C_6H_4\cdot CH_2\cdot N(CH_2Ph)\cdot OH,$$

is oxidised with ferricyanide of potassium, and the product crystallised from alcohol, *benzylisoparanitrobenzaldoxime*,  $O<\begin{array}{l}N\cdot CH_2Ph\\ \vert\\ CH\cdot C_6H_4\cdot NO_2\end{array}$, first separates out in brilliant, yellowish needles melting at 117—118°. The mother liquor then contains a substance which crystallises out in nodular aggregates melting at 93°; this consists of a mixture of equal parts of benzylisoparanitrobenzaldoxime and paranitrobenzylisobenzaldoxime,  $O<\begin{matrix}N\cdot CH_2\cdot C_6H_4\cdot NO_2\\ |\\ CHPh\end{matrix}$. This compound cannot be decomposed by crystallisation from various solvents, but it was shown by Raoult's method to be completely dissociated when dissolved in acetic acid.

When paranitrobenzylisobenzylaldoxime is prepared from β-nitrobenzylhydroxylamine hydrochloride and benzaldehyde, a product is obtained which melts at temperatures varying between 105 and 114°, and is probably a mixture of two "physically" isomeric varieties of the oxime. C. F. B.

Constitution of Carbonylorthamidophenol. By O. Gressly and M. Nencki (*Monatsh*, 11, 253—259; compare Abstr., 1883, 1110; 1887, 135, 245, 477).—The authors have sought to obtain evidence as to whether carbonylorthamidophenol (oxycarbamidophenol, hydroxymethenylamidophenol) has the constitution  $C_6H_4<\begin{matrix}N\\ O\end{matrix}>C\cdot OH$ or  $C_6H_4<\begin{matrix}NH\\ O\end{matrix}>CO$, by investigating the changes which it undergoes in the animal system.

When an aromatic compound contains a carboxyl-group, it passes through the animal system either unchanged or as compounds of glycocine. The homologues of benzene, and the aromatic alcohols, aldehydes, and acids are oxidised in the side-chain, and mostly eliminated as carbonic anhydride. Hydroxy-compounds, especially when they contain no carboxyl group, and phenols are eliminated either as sulphates or as compounds of glycuronic acid. When the substance contains no hydroxyl or carboxyl group and undergoes no oxidation of the side-chain, a hydrogen atom in the benzene ring is displaced by hydroxyl; thus benzene is converted into phenol, indole into indoxyl, and so on. From this it will be seen that if the first of the above formulæ be correct carbonylorthamidophenol should undergo no further oxidation in the animal system, but should be eliminated either as a sulphate or as a compound of glycuronic acid; on the other hand, if the second formula be correct, a hydroxyl group should be substituted for a hydrogen atom in the benzene ring and some such compound as  $OH\cdot C_6H_3<\begin{matrix}NH\\ O\end{matrix}>CO$ should be obtained.

A rabbit received 1 gram of carbonylorthamidophenol per diem, in several doses, and a dog, of 12 kilograms body-weight, received 2—3 grams per diem in like manner. When 6 grams had been administered, the urine was evaporated to a syrup, acidified with hydrochloric acid until it contained 10 per cent. of acid, and heated for an hour in a reflux apparatus. When cold, the solution was shaken with ether, and the ether extract distilled. The residue is a new substance, carbonylortho-hydroxyamidophenol.

Carbonylortho-hydroxyamidophenol, $C_7H_5NO_3$, crystallises from hot water as a powder consisting of aggregates of microscopic rhombic prisms; it is easily soluble in alcohol and in alkaline solutions, from which it is precipitated by acids, and slightly in ether. It dissolves in strong sulphuric acid unchanged, and is precipitated on addition of water. It decomposes with blackening at 265°. Its solution gives a characteristic red colour with chloride of lime, and a purple-red colour, becoming a red precipitate after a time, with Millon's reagent; these reactions can be obtained in urine itself after carbonylorthamidophenol has been administered. Its aqueous solution gives a greenish colour with ferric chloride. In the urine it mostly existed as a sulphate, especially, apparently, in the rabbit's urine; a little existed as a compound of glycuronic acid, and this was more plentiful in the dog's urine, a conclusion arrived at because a glycuronic acid compound would be more difficult to decompose by the hydrochloric acid treatment, and the yield of [illegible] hydroxyamidophenol would then be less, which was the case; moreover, the dog's urine reduced alkaline copper solution more strongly than the rabbit's urine did.

This formation of carbonylortho-hydroxyamidophenol is evidence in favour of the second formula for carbonylorthamidophenol.

A. G. B.

Silver Formanilide. By W. J. Comstock and F. Kleeberg (*Amer. Chem. J.*, 12, 493—502).—This compound can be prepared by dissolving sodium formanilide in 50 per cent. alcohol, and gradually adding, with constant stirring, the theoretical quantity of silver nitrate, in dilute alcoholic solution; or, more quickly, by dissolving the theoretical quantities of formanilide and silver nitrate in dilute alcohol, and slowly stirring in the theoretical quantity of pure sodium hydroxide. When first precipitated, silver formanilide is an amorphous, white powder, which turns grey on exposure to light. It is quite stable at ordinary temperatures, and has the constitution $NPh:CH{\cdot}OAg$, as shown by its behaviour with methyl iodide.

Methylisoformanilide, $NPh:CH{\cdot}OMe$, is obtained when the above-described silver salt is treated with methyl iodide dissolved in a little ether. The resulting paste, on remaining, gradually becomes more fluid, and in 24 hours the reaction is complete. Ether is then added, and the solution filtered from silver iodide. On evaporating the ether, the compound is obtained as a heavy oil boiling at 196—198°. It is isomeric with formylmethylaniline; from which, however, it is easily distinguished, both by its odour, and by its giving with aniline the well-known diphenylformamidine, $NPh:CH{\cdot}NHPh$.

Iodoisoformanilide is formed when finely pulverised silver formanilide is mixed with dry chloroform and 1 mol. of dry iodine is added. Silver iodide immediately forms, and is filtered off. The filtrate is concentrated first on a water-bath; afterwards, in a current of dry air, when a quantity of light-yellow crystals separates. These are washed with ether, and rapidly recrystallised from ether or chloroform. The compound is very unstable, and rapidly gives up iodine; water quickly decomposes it. In all probability, it has the constitution $NH:CH{\cdot}OI$. The melting point could not be determined; but when slowly heated in a tube, very little iodine escapes, and the substance melts at 110°. In this case, however, a second compound, the result of molecular rearrangement, is formed.

Pariodoformanilide is obtained on heating iodoisoformanilide for a few minutes at 115°, or by simply adding formic acid to it. Crystallised from water, it forms white, transparent needles melting at 109—110°.

On dry distillation, silver formanilide yields symmetrical diphenylcarbamide, carbon monoxide, and metallic silver. G. T. M.

Derivatives of Aromatic Amines. By C. PAAL and G. OTTEN (*Ber.*, **23**, 2587—2599).—Butyric chloride reacts with sodacetanilide yielding butyranilide; benzoic chloride, under the same conditions, gives benzanilide.

Ethyl chlorocarbonate and sodacetanilide yield ethyl phenylcarbamate; ethyl chloromalonate is converted into ethyl dicarbinetetracarboxylate when it is treated with the sodium derivative of formanilide, acetanilide, or butyranilide.

Ethyl formanilidoacetate, $COH{\cdot}NPh{\cdot}CH_2{\cdot}COOEt$, is obtained when a benzene solution of ethyl chloracetate is treated with sodioformanilide; it is a brown oil, and boils at 290—295°. The free *acid*, $C_9H_9NO_3$, prepared by hydrolysing the ethereal salt with concentrated alcoholic potash, crystallises from hot water in large, colourless needles, melts at 123—124°, and is readily soluble in ether, alcohol, glacial acetic acid, and concentrated mineral acids. The *sodium* salt, $C_9H_8NO_3Na$, is a crystalline, hygroscopic compound moderately easily soluble in alcohol.

Ethyl acetanilidoacetate, $NPhAc{\cdot}CH_2{\cdot}COOEt$, is formed when a benzene solution of ethyl chloracetate is treated with sodacetanilide; it is a yellow oil, boils at 298—300°, and solidifies to a mass of colourless plates when cooled. The free *acid* (m. p. 190—191) is obtained when the ethyl salt is hydrolysed with alcoholic potash; it has been previously prepared by Rebuffat (*Gazz. Chim.*, 17, 231). The *sodium* salt, $C_{10}H_{10}NO_3Na$, crystallises from dilute alcohol, and is very readily soluble in water. The *barium* salt, $(C_{10}H_{10}NO_3)_2Ba + 3H_2O$, crystallises from water in colourless needles. The copper salt is almost insoluble in water. The *bromo*-derivative,

$$C_6H_4Br{\cdot}NAc{\cdot}CH_2{\cdot}COOH,$$

prepared by brominating the acid, crystallises from glacial acetic acid or dilute alcohol in colourless needles, and melts at 176—177°.

Acetoparatoluidoacetic acid, $C_6H_4Me{\cdot}NAc{\cdot}CH_2{\cdot}COOH$, can be obtained by treating ethyl chloracetate with sodioparatoluidine, and hydrolysing the product with alcoholic potash. It crystallises from hot water in large plates, melts at 174—175°, and is almost insoluble in light petroleum, but more readily in hot ethyl acetate and alcohol. The *sodium* salt, $C_{11}H_{12}NO_3Na + 3H_2O$, crystallises from water in plates, and is very readily soluble.

α-Formanilidopropionic acid, $COH{\cdot}NPh{\cdot}CHMe{\cdot}COOH$, is obtained when the reaction product of ethyl α-bromopropionate and sodioformanilide is hydrolysed with alcoholic potash. It crystallises from ether in large, colourless prisms, and is soluble in alcohol, ether, and hot water. The *barium* salt, $(C_{10}H_{10}NO_3)_2Ba + H_2O$, is a crystalline powder readily soluble in water.

Ethyl α-acetanilidopropionate, NPhAc·CHMe·COOEt, prepared by heating sodioacetanilide with a benzene solution of ethyl α-bromopropionate, is a yellow oil boiling at 294—298°. The corresponding acid $C_{11}H_{13}NO_3$ has been previously prepared by Nastvogel (this vol., p. 1159). The *sodium* salt, $C_{11}H_{12}NO_3Na + 3H_2O$, is a crystalline compound readily soluble in water, but only sparingly in alcohol.

A compound which seems to have the composition $C_{12}H_{12}N_2$ is obtained in small quantities when sodioformanilide or sodacetanilide is suspended in benzene, heated with ethyl α-bromisobutyrate for several hours, and the oily product hydrolysed with alcoholic potash; it crystallises from dilute alcohol in yellow needles, melts at 130—132°, and is soluble in mineral acids; it is not identical with hydrazobenzene. A small quantity of the same substance (m. p. 130—132°) is obtained when ethyl β-iodopropionate or ethyl chloracetoacetate is treated with the sodium derivative of formanilide or acetanilide under the same conditions, and the product hydrolysed with alcoholic potash. F. S. K.

Oxidation of Ketones by Potassium Permanganate in Alkaline Solution. By C. Glücksmann (*Monatsh.*, **11**, 246—252; compare this vol., p. 237).—Acetophenone is easily oxidised to phenylglyoxylic acid under the following conditions:—A solution of potassium permanganate (32 grams) and potassium hydroxide (12 grams) in water (1 litre) is gradually added from a separating funnel to acetophenone (12 grams) suspended in water, with constant shaking; the solution must be kept cool with ice until it has become colourless, when it is filtered from the manganese dioxide, neutralised with sulphuric acid, and evaporated on the water-bath. The concentrated solution is shaken with ether to remove acetophenone, warmed to expel the ether which remains dissolved, and acidified with sulphuric acid to separate as much as possible of the benzoic acid which has been formed. After filtering, the filtrate is thoroughly extracted by ether, and this ethereal solution evaporated; the residue is dissolved in water, and shaken with carbon bisulphide, which extracts the rest of the benzoic acid, leaving a solution of phenylglyoxylic acid, which is crystallised in a vacuum. In two experiments, the yields were 20 and 22 per cent. respectively of the theoretical. The barium salt and phenylhydrazide were prepared so as to leave no doubt as to the identity of the acid.

Peter (Abstr., 1885, 764), Claus and Strohmenger (*Ber.*, **19**, 230), and Buchka (*Ber.*, **20**, 388) have failed to effect the oxidation of acetophenone to phenylglyoxylic acid by potassium permanganate; this the author attributes mainly to the fact that they did not use an excess of acetophenone, thus allowing the phenylglyoxylic acid to be further oxidised.

Buchka and Irish (Abstr., 1887, 483) used potassium ferricyanide, but attributed the formation of the small quantity of phenylglyoxylic acid which they obtained to a secondary reaction, and asserted that acetophenone oxidises according to Popoff's rule. Claus goes so far as to state (this vol., p. 769) that acetophenone cannot be oxidised to phenylglyoxylic acid by potassium permanganate under any circumstances, and, generally, that aromatic alkyl ketones can only be oxidised by potassium permanganate to ketonic acids when the benzene nucleus contains an alkyl group in the ortho-position relatively to the ketone group.

The author points out that the above statements must now be repealed; he suggests that Buchka and Irish would obtain a better yield in alkaline solution, and that Claus would succeed in oxidising many ketones to ketonic acids if he were to employ potassium permanganate in alkaline solution. A. G. B.

Isocinnamic Acid and Allocinnamic Acid. By C. LIEBERMANN (*Ber.*, **23**, 2510—2515).—In preparing isocinnamic acid from the decomposition products of the alkaloids occurring together with cocaine (compare this vol., p. 494), the author has discovered a new acid, isomeric with isocinnamic acid, which he names allocinnamic acid. The material from which this new acid was isolated was a crude acid mixture obtained by decomposing the alkaloïds with hydrochloric acid and extracting the filtered solution with ether; this mixture was first boiled with dilute alkali to decompose ethereal salts, then further treated as previously described (*loc. cit.*), and the new acid finally separated from the isocinnamic acid by fractional crystallisation from hot light petroleum.

Allocinnamic acid, $C_9H_8O_2$, separates from light petroleum in colourless, monosymmetric crystals; $a : b : c = 1{\cdot}5972 : 1 : 1{\cdot}0300$; $\beta = 88° 38\frac{1}{2}'$; it melts at 68°, and is much more sparingly soluble in cold light petroleum than isocinnamic acid, which it resembles very closely in chemical behaviour. The *calcium* salt, $(C_9H_7O_2)_2Ca + 2H_2O$, prepared by neutralising the acid with calcium carbonate and evaporating the solution at 100°, crystallises in colourless needles, loses its water at 90°, and is rather more sparingly soluble than calcium isocinnamate. The *silver* salt, $C_9H_7O_2Ag$, is stable in the light. The acid is immediately oxidised to benzaldehyde by potassium permanganate; when distilled, it is converted into cinnamic acid, but the change takes place more slowly, and rather larger quantities of cinnamene and carbonic anhydride are produced than in the case of isocinnamic acid. When treated with iodine in carbon bisulphide solution, it is transformed into cinnamic acid, and bromine, under the same conditions, converts it into cinnamic acid dibromide. On reduction with sodium amalgam, it gives hydrocinnamic acid, but the change takes place rather more slowly, and a larger quantity of amalgam is required than is the case in the reduction of isocinnamic acid. It is partially converted into cinnamic acid by concentrated sulphuric acid, but about 80 per cent. is resinified.

Both iso- and allo-cinnamic acids are gradually converted into cinnamic acid on exposure to direct sunlight, but the change takes place less rapidly in the case of the allo-acid; in this respect, the acids behave like the alkyl-substituted orthocoumaric acids investigated by Perkin (Trans., 1881, 409), the α-compounds corresponding with isocinnamic acid, and the β-compounds with cinnamic acid. When α-orthomethylcoumaric acid is heated at 90° with iodine (0·1 part) in carbon bisulphide solution for five hours, it is almost completely transformed into the corresponding β-acid; the same change takes place when the α-compound is exposed to the light in alcoholic solution.

Isocinnamic chloride can be obtained by treating a well-cooled solution of the acid in light petroleum with phosphoric chloride; it is an unstable oil and gradually changes into the chloride of cinnamic acid.

Acid *aniline isocinnamate*, $2C_9H_8O_2,C_6H_7N$, is precipitated in long, colourless needles when light petroleum is added to a benzene solution of isocinnamic acid and aniline; it crystallises unchanged from boiling water, melts at 83°, and is only moderately easily soluble in cold water.

Isocinnamic acid seems not to be formed in the synthesis of cinnamic acid by Claisen's method (this vol., p. 891). F. S. K.

Dichlorosalicylic Acid. By J. L. HECHT (*Amer. Chem. J.*, **12**, 502—506).—The author finds that the three dichlorosalicylic acids, described by Rogers (*Inaug. Diss. Göttingen*, 1875), Smith (*Ber.*, **11**, 1225), and Pauli (*Inaug. Diss. Göttingen*, 1878) respectively, until now supposed to be isomerides, are identical, and yield the same dichlorophenol, $[OH : Cl_2 = 1 : 2 : 4]$, on distillation with calcium oxide and sand. The only known dichlorosalicylic acid has consequently the constitution $[COOH : OH : Cl_2 = 1 : 2 : 3 : 5]$; it melts at 214°. G. T. M.

Action of Picric Chloride on Ethyl Sodacetoacetate. By E. DITTRICH (*Ber.*, **23**, 2720—2725).—When ethyl sodacetoacetate (1 mol.) in alcoholic solution is treated with picric chloride ($\frac{2}{3}$ mol.) and the solution evaporated, the residue contains *ethyl trinitrophenylacetoacetate*, $C_6H_2(NO_2)_3\cdot CHAc\cdot COOEt$, as well as the sodium derivative of this substance, $C_6H_2(NO_2)_3\cdot CNaAc\cdot COOEt$. By treatment with water the former is unaffected, whilst the latter dissolves, and its solution yields ethyl trinitrophenylacetoacetate itself when treated with dilute hydrochloric acid. This substance, when pure, forms yellow crystals melting at 98°, soluble in hot alcohol, ether, and benzene. With alkalis, it gives dark, reddish-brown solutions, from which dilute acids precipitate the original substance. It is decomposed when its aqueous solution is boiled. When treated with an equivalent quantity of sodium ethoxide, it yields the above-mentioned sodium derivative, which is a reddish-brown substance.

If, instead of $\frac{2}{3}$ mol. of picric chloride, 1 mol. is used, a sandy substance separates which is insoluble in most solvents, but crystallises from acetic acid in yellowish needles melting at 205° with decomposition; it is *ethyl ditrinitrophenylacetoacetate*,

$$CAc(C_6H_2[NO_2]_3)_2\cdot COOEt.$$

This is insoluble in cold aqueous alkalis; on warming, solution takes place, but the addition of acids does not reprecipitate the original substance. In alcoholic potash it dissolves, but when acids are added, ethyl trinitrophenylacetoacetate is precipitated, picric acid having been formed. Small quantities of a substance melting at 80°, presumably ethyl ditrinitrophenylacetate, are also formed.

When a solution of ethyl trinitrophenylacetoacetate in acetic acid is boiled with sulphuric acid in a reflux apparatus, *trinitrobenzyl methyl ketone*, $C_6H_2(NO_2)_3{\cdot}CH_2{\cdot}COMe$, is formed. It crystallises from alcohol in long, yellowish needles melting at 89°. and dissolving in alkalis to reddish-brown solutions, from which acids reprecipitate the ketone. With phenylhydrazine, it yields a condensation product, $C_{15}H_{13}N_5O_6$, which forms brick-red prisms melting at 125° with decomposition. Only one of the nitro-groups could be reduced; further reduction being attended by decomposition. The reduction was effected by means of the equivalent quantity of stannous chloride. The product $C_9H_9N_3O_5$ when crystallised from alcohol, in which it is very soluble, forms groups of golden-yellow needles melting with decomposition at 214°. C. F. B.

Organic Sulphuretted Compounds. By A. PURGOTTI (*Gazzetta*, **20**, 24—32).—Otto (*Zeit. fur Chemie*, **3**, 251) found that the action of sodium thiosulphate on benzyl chloride resulted in the formation of an impure brominated compound which on distillation with sulphuric acid yielded thiophenol, toluene, stilbene, thionessal, and tollalyl sulphide. When a solution of sodium thiosulphate (38 grams) in water (58 grams) is heated in a reflux condenser with a mixture of benzyl chloride (20 grams) and alcohol (40 grams) until the solutions intermingle, and the whole is then evaporated to dryness on the water-bath, a solid is left, which, after being purified by crystallisation from alcohol, forms white, nacreous tables, consisting of *sodium benzylthiosulphate*, $CH_2Ph{\cdot}S_2O_3Na$. This compound is very soluble in water, and the solution gradually decomposes on boiling; when heated with dilute hydrochloric acid, thiophenol is formed; on dry distillation, it decomposes with evolution of sulphurous anhydride, yielding benzyl bisulphide; on prolonged heating to 100—105°, it is decomposed into benzyl bisulphide and sodium dithionate. Amorphous *silver* and *mercury* salts and crystalline *barium* and *ammonium* salts may be prepared by double decomposition. On boiling a diluted alcoholic solution of the sodium salt with mercuric chloride, the compound $CH_2Ph{\cdot}SHgCl$ is formed.

Benzylthiosulphuric acid, $CH_2Ph{\cdot}S_2O_3H$, prepared from the barium salt crystallises from ether in colourless needles and prisms, and melts at 74—75°. It has a distinctly acid reaction, and is decomposed by boiling with water into thiophenol and sulphuric acid.

Chloranil dissolves in the cold in a concentrated solution of sodium thiosulphate, and on evaporation the solution leaves a black, amorphous residue, which is converted by boiling with hydrochloric acid into an insoluble, uncrystallisable, greenish-yellow compound having approximately the composition $C_6(OH)_2Cl(SH)_3$. This substance is readily soluble in alkalis, and is reprecipitated unchanged from its solutions on addition of hydrochloric acid. It is sparingly soluble in acetone.

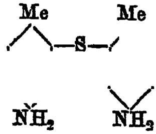
When diazobenzene chloride is warmed with sodium thiosulphate, nitrogen is evolved, a red solution and a black oily compound remaining; the latter, on distillation in a current of steam, yields a mixture of phenyl sulphide and bisulphide; this is entirely converted into benzene sulphide on boiling it for four hours and redistilling. From the red solution, a compound having the composition $C_6H_6SN_2O_3$ and probably identical with Fischer and Romer's hydrazinebenzenesulphonic acid may be obtained. It crystallises in yellow needles.

When sodium sulphide is gradually added to paradiazotoluene, a violent action ensues and the liquid must be kept cold to avoid an explosion. The product is a yellow oil which, on distillation, yields a crystalline compound containing cresyl parasulphide and parahydrosulphide.

Sodium sulphide has a similar action on orthodiazotoluene, cresyl orthosulphide and hydrosulphide being formed; the former is a liquid boiling at 285°, and readily soluble in chloroform, ether, and carbon bisulphide, but only sparingly in alcohol and in acetic acid. The *mercuric salt* of the hydrosulphide, $(C_6H_4MeS)_2Hg$, crystallises in white needles, the *ethyl* salt, $C_6H_4Me{\cdot}SEt$, obtained by converting the hydrosulphide into a sodium salt and boiling with ethyl iodide and alcohol, is a heavy liquid which boils at 120°, and has an odour of onions.

Orthocresylethylsulphine, $S(C_6H_4Me)_2EtI$, prepared by heating orthocresyl sulphide with ethyl iodide, is an insoluble compound crystallising in needles; *orthocresylsulphone*, $SO_2(C_6H_4Me)_2$, obtained by oxidising a dilute acetic acid solution of the sulphide with potassium permanganate, crystallises in needles melting at 134—135°.

When Merz and Weith's thioparatoluidine (Abstr., 1871, 566) is diazotised and the product heated with alcohol, it is decomposed with evolution of nitrogen, and on adding water to the residue, cresyl orthosulphide is precipitated; the constitution of thioparatoluidine is, therefore,



S. B. A. A.

Phenyldithienyl. By A. Renard (*Compt. rend.*, **111**, 48—49).—Phenyldithienyl is obtained, together with phenylthiophen, by the action of sulphur on toluene at a dull red heat (this vol., p. 134). That portion of the product which is least soluble in alcohol is exhausted with benzene, and the phenyldithienyl which dissolves is purified by recrystallisation from pure benzene. It has the composition $C_4SH_2Ph{\cdot}C_4SH_3$, and forms colourless plates which melt at 209°, sublime easily, and are almost insoluble in alcohol, ether, and light petroleum, slightly soluble in chloroform or ethyl acetate, and very soluble in boiling benzene or toluene. With isatin and sulphuric acid, phenyldithienyl gives a blue coloration, and with phenanthraquinone, a green coloration. It is not attacked by alkaline or neutral permanganate, but is completely oxidised by chromic anhydride in acetic acid. If the acetic acid is previously diluted with an equal volume of water, a small quantity of benzoic acid is formed. *Tribromphenyldithienyl*, $C_{14}S_2H_7Br_3$, is obtained by treating phenyldithienyl with excess of bromine and leaving it exposed to the air until the hydrogen bromide and excess of bromine have escaped. The residue is boiled with alcoholic potash, washed with water, dried, and crystallised from carbon bisulphide. It forms white crystals which melt at 320°, are almost insoluble in alcohol, benzene, and chloroform, and slightly soluble in carbon bisulphide. With isatin and sulphuric acid, it gives no coloration. *Dinitrophenyldithienyl* is obtained by the action of ordinary fuming nitric acid and is purified by washing it with ammonium carbonate solution, water, and alcohol. It forms a yellow powder which melts at 273°, is insoluble in ether and light petroleum, very slightly soluble in alcohol, ethyl acetate, and chloroform, and somewhat more soluble in benzene. It gives no coloration with isatin and sulphuric acid, but, like the dinitrothiophens, when treated with an alkaline hydroxide in presence of alcohol, it gives a red coloration which is discharged by acids. *Phenyldithienyldisulphonic acid*, $C_{14}S_2H_8(SO_3H)_2$, is obtained by the action of fuming sulphuric acid in the cold, or of the ordinary acid at 150°. Its barium salt forms colourless crystals very soluble in water. C. H. B.

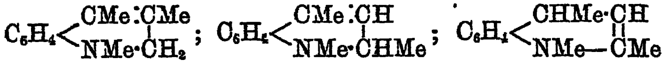
Methylation of the Indoles. By E. FISCHER and J. MEYER (*Ber.*, 23, 2628—2634).—It has previously been shown by E. Fischer and Steche (Abstr., 1888, 298) that 2′-methylindole is converted by methyl iodide into a compound, for which they found the formula $C_{11}H_{13}N$, and which from its behaviour appeared to be a derivative of dihydroquinoline, having the formula

$$C_6H_4<\begin{matrix}CH{=}CMe\\ NMe{\cdot}CH_2\end{matrix}.$$

They found further that 2′ : 3′-dimethylindole also yields dihydroquinoline derivatives closely resembling the above compound. The renewed investigation of the subject by the authors has shown that the compound obtained from 2′-methylindole and methyl iodide has the formula $C_{12}H_{15}N$ instead of $C_{11}H_{13}N$, and that it is identical with the compound obtained from 2′ : 3′-dimethylindole. It must therefore be a trimethyldihydroquinoline, and not, as previously supposed, a dimethyl derivative.

In the preparation of trimethyldihydroquinoline, the method previously given was adhered to. The numbers required for the formulæ $C_{11}H_{13}N$ and $C_{12}H_{15}N$ do not differ sufficiently to allow of any conclusion as to composition being drawn from the analysis, but by the action of hydrogen iodide in ethereal solution, the base yields a crystalline *hydriodide*, which, from a determination of the iodine, must have the formula $C_{12}H_{15}N,HI$. As above stated, it is obtained in a similar manner from 2′ : 3′-dimethylindole, and may also be prepared, although with greater difficulty, from scatole and 1′-methylindole. On reduction with tin and hydrochloric acid, it readily yields trimethyltetrahydroquinoline (previously described as a dimethyl compound). This yields a well-crystallised *methiodide*, the analysis of which showed its composition to be $C_{12}H_{17}N,MeI$.

The formation of trimethyldihydroquinoline is represented by the equation $C_9H_9N + 3CH_3I = C_{12}H_{15}N + 3HI$. One of the methyl groups enters as methylene into the indole ring, a second combines with the nitrogen, whilst the third unites with one of the carbon atoms of the indole ring. The methylene group may either enter into the ring between the nitrogen and carbon atoms, or between the doubly-linked carbon atoms, giving a choice between the three formulæ:—



$$C_6H_4{<}\begin{array}{l}CMe{:}CMe\\ \quad\ \ \vert\qquad\ \vert\\ NMe{\cdot}CH_2\end{array};\quad C_6H_4{<}\begin{array}{l}CMe{:}CH\\ \quad\ \ \vert\qquad\ \vert\\ NMe{\cdot}CHMe\end{array};\quad C_6H_4{<}\begin{array}{l}CHMe{\cdot}CH\\ \quad\ \ \vert\qquad\ \Vert\\ NMe{-}CMe\end{array}.$$

An attempt was made to ascertain which of these formulæ is correct by converting 2′ : 4′-dimethylquinoline and 3′ : 4′-dimethylquinoline into the corresponding trimethyltetrahydroquinolines, and comparing them with the compound obtained by the reduction of trimethyldihydroquinoline. It was found, however, that all three compounds are different, that obtained from 2′ : 4′-dimethylquinoline melting 40°, and that from 3′ : 4′-dimethylquinoline 50°, lower than the compound from trimethyldihydroquinoline. No conclusion as to the position of the methyl groups can therefore be obtained in this manner.

H. G. C.

Derivatives of Diphenylmethane and Benzophenone. By W. Staedel and E. Haase (*Ber.*, 23, 2577—2579).—The authors give in tabular form the names and melting points of the various nitro-, amido-, acetamido-, and hydroxy-compounds which they have prepared from diphenylmethane and benzophenone (compare Abstr., 1883, 990).

F. S. K.

Reduction of Nitriles. By M. Freund and P. Remse (*Ber.*, 23, 2859—2865; compare this vol., p. 1388).—Dibenzyl is prepared by dissolving *α*-phenylcinnamonitrile (30 grams) in alcohol, and gradually adding sodium (70 grams), so that a regular, steady evolution of hydrogen takes place; the product is treated with water and distilled in a current of steam, the solid portion of the distillate is washed with hydrochloric acid, and crystallised from alcohol; the yield is 75 per cent. of theory. On treating the nitrile with 2·5 parts of sodium and allowing the reaction to proceed as quickly as possible, *diphenylpropylamine*, $CH_2Ph{\cdot}CHPh{\cdot}CH_2{\cdot}NH_2$, is formed; it is a colourless, viscid liquid which boils at 315—317°, and is miscible with alcohol, chloroform, or ether. The *hydrochloride* is deposited from concentrated hydrochloric acid in white needles melting at 188—190°. The *platinochloride* forms pale-yellow crystals which decompose at 153°. The *aurochloride* crystallises in golden-yellow plates melting at 144—145°. The *mercurochloride* is obtained as a white, crystalline powder which melts at 107°. *Diphenylpropylcarbamide*,

$$CH_2Ph{\cdot}CHPh{\cdot}CH_2{\cdot}NH{\cdot}CO{\cdot}NH_2,$$

is prepared by the action of potassium cyanate on the hydrochloride; it crystallises in slender, white needles melting at 112°. *Diphenylpropylphenylthiocarbamide*, $CH_2Ph{\cdot}CHPh{\cdot}CH_2{\cdot}NH{\cdot}CS{\cdot}NHPh$, crystallises from alcohol in colourless cubes melting at 129°. *Diphenylpropyloxamide*, $C_2O_2(NH{\cdot}CH_2{\cdot}CHPh{\cdot}CH_2Ph)_2$, is formed by the action of ethyl oxalate on the free base, and is deposited from alcohol in white crystals which melt at 115—116°. *Diacetyldiphenylpropylamine*,

$CH_2Ph\cdot CHPh\cdot CH_2\cdot NAc_2$, is prepared by the action of sodium acetate and acetic anhydride; it crystallises from alcohol in slender, white needles melting at 85°. *Diphenylpropyl alcohol*, $CH_2Ph\cdot CHPh\cdot CH_2\cdot OH$, is obtained on treating the amine hydrochloride with silver nitrite; it is a slightly yellow, viscid liquid boiling at 300—302°.

β-Phenyl-γ-anisylpropylamine, $OMe\cdot C_6H_4\cdot CH_2\cdot CHPh\cdot CH_2\cdot NH_2$, is prepared by the action of sodium on phenylanisacrylonitrile in alcoholic solution; it is a yellow, oily liquid, and decomposes on distillation; the *hydrochloride* is also unstable. The *platinochloride* crystallises from water in small, yellow needles which melt at 195° with decomposition. The *aurochloride* is deposited in golden-yellow plates melting at 87°. If the reduction of α-phenylanisacrylonitrile is effected more slowly, *phenylanisylethane*, $CH_2Ph\cdot CH_2\cdot C_6H_4\cdot OMe$, is formed; it is soluble in ether, chloroform, or benzene, and crystallises from alcohol in colourless plates melting at 61°; the yield is 57 per cent. of the nitrile employed. J. B. T.

Triphenylbenzene. By E. Mellin (*Ber.*, **23**, 2533—2536).—Benzoic acid (0·6 gram) is formed when triphenylbenzene (1 gram) is oxidised with chromic acid in warm glacial acetic acid solution.

Dodecahydrotriphenylbenzene, $C_{24}H_{30}$, can be prepared by heating triphenylbenzene at 270—280° for 16 hours with hydriodic acid and amorphous phosphorus. It is an oil with an aromatic odour, and it gradually solidifies in the cold; it is not acted on by cold concentrated nitric acid, but on warming nitro-derivatives are formed. It is converted into sulphonic acids by hot fuming sulphuric acid, but no action takes place in the cold; on oxidation with chromic acid in boiling glacial acetic acid solution, it yields benzoic acid.

Eikosihydrotriphenylbenzene, $C_{24}H_{38}$, is obtained as an oil when the reduction of triphenylbenzene under the above conditions is allowed to proceed for 32 hours.

Tetranitrotriphenylbenzene, $C_{24}H_{14}(NO_2)_4$, is formed, together with an isomeride melting at 108° (see below), when triphenylbenzene is nitrated in glacial acetic acid solution. It crystallises from nitrobenzene, aniline, and ethyl benzoate in pale yellow needles, melts above 370°, and is only very sparingly soluble in all ordinary solvents.

The *tetramido*-derivative, $C_{24}H_{14}(NH_2)_4$, prepared by reducing the nitro-compound with tin and hydrochloric acid in glacial acetic acid solution, crystallises from alcohol in small, colourless needles, and melts at 137—138°. The *octacetyl*-derivative, $C_{24}H_{14}(NAc_2)_4$, is formed when the amido-compound is boiled for six hours with sodium acetate and glacial acetic acid; it crystallises in colourless, microscopic needles, and melts at 156—158°.

Tetranitrotriphenylbenzene, $C_{24}H_{14}(NO_2)_4$, remains in the acid mother liquors from the nitro-compound described above, and is precipitated on the addition of water; it crystallises from alcohol in small needles, melts at 108° with decomposition, and is soluble in ether, alcohol, benzene, and glacial acetic acid. The *tetramido*-compound, $C_{24}H_{14}(NH_2)_4$, crystallises from dilute alcohol in yellowish needles, melts at 96—98° with decomposition, and rapidly darkens on exposure to the air. The *octacetyl*-derivative, $C_{24}H_{14}(NAc_2)_4$, separates from dilute acetic acid in granular crystals, melts at 142—143°, and is soluble in alcohol and ether.

Triphenylbenzenedisulphonic acid was prepared by treating the hydrocarbon with fuming sulphuric acid at 100°; the *barium* salt, $C_{24}H_{16}(SO_3)_2Ba$, crystallises from very dilute alcohol in small, colourless plates.

F. S. K.

Constitution of Naphthalene. By A. CLAUS (*J. pr. Chem.* [2], **42**, 24—49).—In this paper, the author criticises the views recently put forward by Bamberger (this vol., p. 1299); he admits the probability that one of the nuclei in naphthalene is a benzene ring, and proceeds to discuss the structure of the naphthalene derivatives on the supposition that they contain his "diagonal" benzene ring.

A. G. B.

Constitution of Dinitro-β-naphthol. By E. LOEWE (*Ber.*, **23**, 2542—2546).—*Barium dinitro-β-naphthol*, $[C_{10}H_5(NO_2)_2\cdot O]_2Ba + H_2O$, is obtained when a solution of potassium dinitro-β naphthol, prepared as described by Graebe and Drews (Abstr., 1884, 1035), is treated with barium chloride; it crystallises in orange needles, and loses its water at 100°.

Diamido-β-naphthol hydrochloride, $OH\cdot C_{10}H_5(NH_2)_2,2HCl$, prepared by reducing the nitro-compound with tin and hydrochloric acid, crystallises in almost colourless needles; the free base readily oxidises on exposure to the air. The *triacetyl* derivative, $OAc\cdot C_{10}H_5(NHAc)_2$, crystallises from glacial acetic acid in small needles, melts at 203°, and is sparingly soluble in alcohol, and insoluble in water. The *tribenzoyl* derivative, $OBz\cdot C_{10}H_5(NHBz)_2$, crystallises from glacial acetic acid in colourless plates, melts at 265°, and is only sparingly soluble in alcohol and water.

Diamido-β-naphthylamine hydrochloride, obtained by reducing dinitro-β-naphthylamine (compare Graebe and Drews, *loc. cit.*) with tin and hydrochloric acid, crystallises from water in yellowish needles which, after being kept for a long time over soda-lime, have the composition $C_{10}H_5(NH_2)_3,2HCl$. The *sulphate*, $2C_{10}H_5(NH_2)_3,3H_2SO_4$, is crystalline, and only very sparingly soluble in boiling water. The *triacetyl* derivative, $C_{10}H_5(NHAc)_3$, crystallises from glacial acetic acid in colourless needles, and melts at 280° with decomposition. The *tribenzoyl* derivative, $C_{10}H_5(NHBz)_3$, crystallises in yellowish needles, melts at 277°, and is sparingly soluble in alcohol and water.

Amidonaphthaphenanthrazine, $C_{24}H_{15}N_3$, is formed by the condensation of diamido-β-naphthylamine and phenanthraquinone in warm glacial acetic acid solution. It separates from aniline in golden crystals, and dissolves in hydrochloric acid with a reddish-brown, and in concentrated sulphuric acid with a violet coloration; it sublimes readily, and its ethereal solution is fluorescent. The formation of this compound proves that one of the nitro-groups in dinitro-β-naphthol is in the ortho-position relatively to the hydroxyl group.

F. S. K.

Theory of the Truxillic Acids. By C. LIEBERMANN (*Ber.*, **23**, 2516—2518).—The author points out that, assuming that the truxillic acids are tetramethylene derivatives, and applying the principles laid down by Baeyer in his discussion of the constitution of hexamethylene derivatives to the tetramethylene ring, there are 11 theoretically possible truxillic acids, four of which are already known; the constitution of the isomerides is given. F. S. K.

Formation of Anthraquinone under certain Conditions. By L. H. Friedburg (*Chem. Centr.*, 1890, ii, 9; from *J. Amer. Chem. Soc.*, **12**, 26—43).—In the reaction between phenanthraquinone, α-thiotolen, and concentrated sulphuric acid, the dye formed reacts with lead chromate, forming anthraquinone, and the author considers it probable that this is formed exclusively from the thiotolen, and not from the phenanthraquinone. J. W. L.

Benzyloxanthranol. By C. Bach (*Ber.* **23**, 2527—2530; compare this vol., p. 1144).—*Benzyloxanthranol chloride*,

$$C_6H_4<\begin{array}{l}CCl(C_7H_7)\\CO\cdot C_6H_4—\end{array}>,$$

is formed when finely-divided benzyloxanthranol is treated with phosphoric chloride. It crystallises from light petroleum in colourless plates, melts at 95—102°, and is soluble in benzene, yielding a solution which shows a blue fluorescence; it dissolves in concentrated sulphuric acid with a red coloration, and it is readily decomposed by water.

Benzyldihydroanthranol,  $C_6H_4<\begin{array}{l}CH(C_7H_7)\\CH(OH)-\end{array}>C_6H_4$, prepared by reducing benzyloxanthranol with zinc-dust and ammonium hydrate, or with sodium amalgam in alcoholic solution, crystallises from a mixture of benzene and light petroleum in yellowish needles, decomposes at 130—140°, and readily oxidises on exposure to the air; it dissolves in concentrated sulphuric acid yielding a yellow solution which quickly turns green, and, when boiled with dilute acetic acid, it is decomposed quantitatively into benzylanthracene and water.

Benzylanthranol,  $C_6H_4<\begin{array}{l}C(C_7H_7)\\\,|\\C(OH)-\end{array}>C_6H_4$, can be obtained by treating bromobenzyleneanthrone (bromodihydrobenzyloxanthranol) with sodium amalgam in cold alcoholic solution; it crystallises from benzene in yellow needles, melts at 183—184°, is readily soluble in alcohol, ether, and glacial acetic acid, and dissolves in concentrated sulphuric acid with a yellow coloration; it is oxidised to benzyloxyanthranol on exposure to the air.

Ethoxybenzyleneanthrone,  $C_6H_4<\begin{array}{l}C(CPh\cdot OEt)\\CO\cdot C_6H_4——\end{array}>$, prepared by warming bromobenzyleneanthrone with sodium ethoxide in alcoholic solution, crystallises from alcohol in yellow plates, melts at 171—173° with decomposition, and is readily soluble in ether, alcohol, benzene, and glacial acetic acid; it dissolves in concentrated sulphuric acid yielding a blood-red solution.

Amidobenzyleneanthrone,  $C_6H_4<\begin{array}{l}C(CPh\cdot NH_2)\\CO\cdot C_6H_4——\end{array}>$, is precipitated as an oil, when anhydrous ammonia is passed into a benzene solution of bromobenzyleneanthrone; it separates from a mixture of benzene and light petroleum as an amorphous, orange powder, melts at 150—152°, and dissolves in concentrated sulphuric acid with a violet-red coloration.

Benzylanthracene dihydride,  $C_6H_4<\genfrac{}{}{0pt}{}{CH(C_7H_7)}{CH_2\cdot C_6H_4}>$, is obtained when benzylanthracene is reduced with sodium amalgam in boiling alcoholic solution, or with hydriodic acid and amorphous phosphorus; it crystallises from alcohol in prismatic needles, melts at 110—111°, and dissolves in warm concentrated sulphuric acid with a dark-green coloration. F. S. K.

Mesoanthramine. By F. GOLDMANN (*Ber.*, 23, 2522—2526).—*Mesoanthramine*,  $C_6H_4<\begin{matrix}C(NH_2)\\ |\\ CH\cdot C_6H_4\end{matrix}>$, can be obtained by heating finely-divided anthranol at 200° for about 22 hours with concentrated aqueous ammonia (20 parts); it is purified by converting it into the hydrochloride. It crystallises from cold, dilute alcohol in golden plates, darkens on exposure to the air, and decomposes at about 215°; it is only very sparingly soluble in boiling water, but very readily in ether, benzene, alcohol, and chloroform, the yellow solutions showing a green fluorescence. On oxidation with chromic acid in glacial acetic acid solution, it is converted into anthraquinone. The *hydrochloride*, $C_{14}H_9\cdot NH_2,HCl$, crystallises in colourless needles, is only sparingly soluble in alcohol and boiling hydrochloric acid, and is decomposed by cold water or on exposure to the air; on adding diazobenzenesulphonic acid to a cold alcoholic solution of this salt, a magenta-red coloration is immediately produced, and then a red precipitate, which is insoluble in water and alcohol, but soluble in dilute ammonia, yielding a greenish-yellow solution. The *acetyl* derivative, $C_{14}H_9\cdot NHAc$, prepared by dissolving the base in cold acetic anhydride, crystallises from alcohol in colourless needles, melts at 273—274°, and is rather sparingly soluble in alcohol and benzene; it is very stable, and, when boiled with alcoholic potash, yields a yellow, crystalline compound—probably the potassium derivative—which, when treated with water, is reconverted into the acetyl derivative.

The *diacetyl* derivative, $C_{14}H_9\cdot NAc_2$, obtained by boiling the base with acetic anhydride, crystallises from dilute alcohol in colourless plates, melts at 159°, and is readily soluble in most ordinary solvents except water; it is converted into the monacetyl derivative by boiling alcoholic potash.

Mesoanthramine hydride, $C_{14}H_{11}\cdot NH_2$, is formed when mesoanthramine is boiled with sodium amalgam in alcoholic solution; it crystallises from dilute alcohol in colourless needles, melts at 92°, and is readily soluble in alcohol, ether, and benzene. The hydrochloride, $C_{14}H_{11}\cdot NH_2,HCl$, crystallises in colourless needles, and is readily soluble in water; when an aqueous solution of this salt is boiled with hydrochloric acid, it is decomposed quantitatively into anthracene and ammonia. F. S. K.

Rotatory Power of Camphor when Dissolved in Various Oils. By P. CHABOT (*Compt. rend.*, **111**, 231—233).—The rotatory power of solutions of camphor in olive oil, oil of sweet almonds, and grape-seed oil is practically proportional to their concentration. If $p =$ the percentage amount of camphor in the solution, and α the rotatory power for D, of a column 20 cm. long, then, with olive oil, $\alpha = 10' + p\ 1^\circ\ 1'$; with almond oil, $\alpha = p$; and with grape-seed oil, $\alpha = 36' + p$. Saturated solutions contain the following percentage amounts of camphor: olive oil, 26·93; almond oil, 28·53; and grape-seed oil, 28·80. The molecular rotatory powers of camphor in solution of the three oils are as follows:—

	Olive oil.	Almond oil.	Grape-seed oil.
3 per cent.	55° 42′	56° 47′	54° 24′
20 per cent.	55 12	54 19	54 7

The molecular rotatory power varies little with the concentration, but, as usual, is greater in more dilute solutions. C. H. B.

Combination of Camphor with Phenols. By E. LÉGER (*Compt. rend*, **111**, 109—111).—Camphor and the phenol are melted together in the calculated proportions in closed vessels. Under these conditions, compounds are formed which decompose easily under the influence of heat, or when treated with solvents or with alkalis. That definite compounds are formed is, however, shown by the fact that the liquid products contain their constituents in molecular proportions, and that in those cases where they crystallise the composition of the first crystals is the same as that of the last. The addition of phenols to alcoholic solutions of camphor reduces the rotatory power of the latter to one-half. The compositions of the various products were determined by means of the polarimeter, and the method will be described in detail subsequently.

Phenol monocamphoride, $C_6H_6O,C_{10}H_{16}O$, is a colourless liquid, which crystallises only at about -23°; sp. gr. at about $0^\circ = 1·0205$; $[\alpha]_D = +20^\circ$. *Phenol hemicamphoride*, $2C_6H_6O,C_{10}H_{16}O$, a colourless liquid which does not solidify at -50°; sp. gr. at $0^\circ = 1·040$; $[\alpha]_D = +10^\circ·5$. It combines with camphor to form the monocamphoride; if mixed with excess of phenol, the latter dissolves, but when the liquid is cooled to -25°, it separates distinctly into phenol hemicamphoride and phenol. *Resorcinol monocamphoride*, $C_6H_6O_2,C_{10}H_{16}O$, forms large, thin, hygroscopic, rectangular lamellæ, which become liquid when mixed with a small quantity of water, and are decomposed by a large quantity with separation of camphor. It melts at about 29°, but can remain for a long time in superfusion at 15°; rotatory power in alcoholic solution, $[\alpha]_D = +22·5^\circ$. *Resorcinol dicamphoride*, a syrupy, colourless liquid, which forms large, hexagonal crystals at 0°; sp. gr. at $15^\circ = 1·0366$; $[\alpha]_D = +25·9^\circ$. *α-Naphthol camphoride*, $C_{10}H_8O,C_{10}H_{16}O$, is a slightly coloured, syrupy liquid, which does not solidify at -16°, and is not decomposed by water; sp. gr. at $0^\circ = 1·0327$; $[\alpha]_D = +10·5^\circ$. It dissolves α-naphthol, which separates in short, rhombic prisms (Wyrouboff). *β-Naphthol camphoride*, $3C_{10}H_8O,5C_{10}H_{16}O$, a liquid very similar to the preceding compound, sp. gr. at 0° = 1·0396; $[\alpha]_D = +22·5°$. It dissolves β-naphthol, which separates from it in somewhat large, tabular crystals. *Salicylic camphoride*, $C_7H_6O_3,2C_{10}H_{16}O$, a white, nacreous mass of long, thin, microscopic needles, which melts at about 0°, and is only partially decomposed even by boiling water. Its rotatory power in alcoholic solution is $[\alpha]_D = +27·3°$.

Salol seems to form a similar compound, but its composition has not yet been determined. Salol crystallises from salol camphoride in bulky, irregular crystals of the rhombic system, and some measurements of these by Wyrouboff are given. C. H. B.

Russian Oil of Peppermint. By H. ANDRES (*Chem. Centr.*, 1890, ii, 63: from *Pharm. Zeit. Russ.*, **29**, 341—343).—The oil which the author examined was obtained from the fresh plant. It is greenish-yellow; sp. gr. = 0·915 at 15°; $[\alpha]_D = -17·13°$. The principal distillates are obtained at 160—165°, 173—175°, 203—206°, and 206—209°. The fraction passing over between 173—175° has the highest specific rotation, and contains the terpene $C_{10}H_{16}$; sp. gr. = 0·8667 at 4°, and = 0·8571 at 20° (water at 4° = 1); specific rotation in 10 cm. tube at 20° = $[\alpha]_D = -41·19°$. The tetrabromide of this terpene melts at 102°; $[\alpha]_D = -18·71°$; the inactive dihydrochloride, $C_{10}H_{16},2HCl$, melts at 50°; the nitrosyl chloride, $C_{10}H_{16}NOCl$, melts at 103°, and has the specific rotation −205·28°. These reactions, together with the properties of the levorotatory nitrosoterpenes melting at 72°, prove the identity of the terpene of oil of peppermint with the terpenes which Wallach (Abstr, 1889, 1069) has described. The fraction 160—165° consists of a mixture of terpene and menthene, $C_{10}H_{18}$. The presence of the latter is proved by the preparation of the dibromomenthene $C_{10}H_{18}Br_2$ and the chloromenthyl $C_{10}H_{19}Cl$ (K_{100} = 130—140°; sp. gr = 0·9381 at 20°). From the fractions 203—206° and 206—209°, menthone and menthol are obtained. Hydroxylamine unites with the former forming menthoxime, by which means the two compounds are separated. Hydrochloric acid liberates menthone from the oxime; it boils at 206—208°; sp. gr. = 0·8998, 20/20°; $[\alpha]_D = +8·04$. J. W. L.

Conversion of Pyrroline into its Homologues. By M. DENNSTEDT (*Ber.*, **23**, 2562—2574).—When a mixture of the vapours of pyrroline and alcohol is passed over heated zinc-dust, a liquid consisting of various homologues of pyrroline is obtained, and a large quantity of ethylene is evolved. The experiment was carried out in the following manner:—A long glass tube is bent at a right angle, and the shorter limb is loosely filled with copper turnings, in the longer limb zinc-dust being placed in such a way that it forms a layer occupying about one-third of the breadth of the tube. The longer limb is then heated in a combustion furnace at about 270—280°, and a mixture of equal volumes of alcohol and pyrroline dropped into the shorter limb, which is placed vertically and connected by means of a cork with a stoppered funnel; the products are collected in a receiver provided with a reflux condenser. With an apparatus of this kind, 100—120 c.c. of the liquid mixture can be treated without renewing the zinc-dust.

The liquid in the receiver begins to boil at about 60°; the portion passing over below 135° was employed in subsequent operations; the remainder, after repeated fractional distillation, was separated into the following constituents, 100 grams of pyrroline having been employed.

(1.) A liquid (15 grams) boiling at 163—165°, which is identical with the ethylpyrroline obtained by Ciamician and Zanetti (Abstr., 1889, 727) from pyrroline and ethyl iodide.

(2.) A liquid (3 to 5 grams) boiling at 175—177°, which consists of a mixture of ethyl- and diethyl-pyrroline.

(3.) A diethylpyrroline (8 to 10 grams) boiling at 185—187°, which, when heated with acetic anhydride and sodium acetate at 190°, yields an *n*-acetyl and a *c*-acetyl-derivative; the latter separates from benzene or dilute alcohol in monosymmetric crystals, melts at 98°, and boils at about 295—300°.

(4.) A triethylpyrroline (5 grams) boiling at 200—205°, which yields an *n*-acetyl and a *c*-acetyl-derivative; the latter separates from alcohol in well-defined monosymmetric crystals, melts at 138°, and boils above 300°.

(5.) A liquid (5 grams) boiling at 210—240°, the nature of which has not yet been determined.

Methyl alcohol and pyrroline give products analogous to those obtained from ethyl alcohol and pyrroline under the same conditions, but the various compounds have not been completely separated from one another.

When benzene is heated with alcohol in the manner described above, only very small quantities of higher-boiling hydrocarbons are formed, and the products cannot be isolated except with great difficulty. Phenol under the same conditions gives small quantities of at least two ethyl phenols; aniline reacts both with methyl and ethyl alcohol, yielding considerable quantities of methyl- and ethylaniline, benzonitrile being also formed when methyl alcohol is employed.

When a mixture of the vapours of pyridine and ethyl alcohol is passed over heated zinc-dust, small quantities of α-ethylpyridine and $\alpha\gamma$-diethylpyridine are formed, but most of the pyridine remains unchanged.

Piperidine reacts with alcohol much more readily than pyridine, about 50 per cent. of the base being changed; the following compounds were isolated from the reaction product:—(1.) Considerable quantities of *n*-ethylpiperidine boiling at 128°. The *platinochloride*, $(C_7H_{15}N)_2,H_2PtCl_6$, forms bright-red, well-defined crystals, melting at 202°. The *aurochloride*, $C_7H_{15}N,HAuCl_4$, separates from dilute hydrochloric acid in dark-yellow crystals, and melts at 106—107°. The *picrate*, $C_7H_{15}N,C_6H_3N_3O_7$, crystallises from hot water, and melts at 163°.

(2.) Very small quantities of two liquids boiling at 140—146° and 152—158° respectively, the nature of which was not determined.

(3.) A rather larger quantity of a liquid boiling at 165—175°, which is a mixture of two diethylpiperidines. The two compounds can be separated by means of their picrates, both of which have the composition $C_9H_{19}N,C_6H_3N_3O_7$; the one crystallises in long needles melting at 89—90°, the other forms small compact crystals melting at 105—107°.

(4.) A diethylpiperidine boiling at 180—190°, the hydrochloride of which is deliquescent; the aurochloride is an oil, but the picrate crystallises from water in long, yellow needles, and melts at 75—76°.

F. S. K.

Derivatives of Dihydropyrroline. By F. ANDERLINI (*Gazzetta*, 20, 69—73).—*Dihydropyrroline hydrochloride*, described by Ciamician and Dennstedt, forms a deliquescent, crystalline mass, which decomposes on heating with evolution of vapours which give the pinewood reaction. It is decomposed by heating with concentrated hydrochloric acid at 130—140°, and is probably converted in part into pyrroline. The *aurochloride*, $C_4NH_7,HAuCl_4$, may be obtained in orange-yellow crystals by concentrating its solution in dilute hydrochloric acid in a vacuum, but it is partially decomposed when heated on the water-bath. It melts at 152°, and is freely soluble in water; the *picrate* is a yellow salt, freely soluble in water or alcohol, and melts at 156°.

Benzoyldihydropyrroline.—When dihydropyrroline hydrochloride (3 grams) is heated with benzoic chloride (8 grams) for about seven hours at 110°, the product is a brown syrup from which a portion distilling between 160° and 161° under a pressure of about 2 mm. may be separated by fractionation. This portion has the composition C_4NH_6Bz. It is a heavy, aromatic oil, soluble in ether but not in water; it dissolves in hydrochloric acid forming a difficultly crystallisable hydrochloride, which yields yellow oily compounds with platinic and auric chlorides, with picric acid, and with the double iodide of potassium and mercury or cadmium, and a white precipitate with mercuric chloride.

Acetic chloride acts on dihydropyrroline in a different way from benzoic chloride, the products of the reaction being a complex mixture of various compounds.

Benzylhydropyrroline.—When dihydropyrroline is treated with benzyl chloride, and the solid product of the reaction separated and fractionally distilled, a small quantity of an oily liquid passes over at about 150°. This fraction is insoluble in water, but dissolves in dilute hydrochloric acid. The *aurochloride*, $C_4NH_6{\cdot}CH_2Ph,HAuCl_4$, crystallises in yellow needles melting at 111°; it is very freely soluble in water. The behaviour of dihydropyrroline with acetic and benzyl chlorides indicates that several of the atoms of hydrogen may be substituted by organic radicles.

S. B. A. A.

Tertiary Pyrroline Derivatives. By C. W. ZANETTI (*Gazzetta*, 20, 64—69).—1-*Ethyldiacetylpyrroline*, $C_4NH_2Ac_2Et$, is prepared by heating 1-ethylpyrroline (1 part) with acetic anhydride (10 parts) in a sealed tube for seven hours at 250°. From the product a heavy oil may be extracted, which by rectification can be separated into fractions boiling between 200—285° and 285—310° respectively. On distilling the latter fraction under a pressure of 29 mm., the diacetyl derivative passes over at 183°. It is a yellowish oil with an odour of bitter almonds, and solidifies after a time into a crystalline mass melting at 58—59°; it is very soluble in alcohol, ether, benzene, and light petroleum, but is less soluble in water. The fraction (200—285°) probably contains a mixture of monacetyl and diacetyl derivatives.

1-*Methylpyrrolketonedicarboxylic acid*, $C_4NH_2MeCO(COOH)_2$. When Ciamician and Silber's 1-methyldiacetylpyrroline (Abstr. 1877, 843) is oxidised with potassium permanganate in an alkaline solution, and the product acidified and extracted with ether, a compound is obtained in yellow crusts, which have a decided acid reaction, dissolve with effervescence in solutions of the alkaline carbonates, turn brown at 100°, and decompose at 165°. It is very soluble in water, alcohol, ether, &c. The acid cannot be obtained sufficiently pure for analysis; the *silver* salt has the composition $C_8H_5AgNO_5$. By neutralising the acid with ammonia, an aqueous solution of the ammonium salt is obtained from which salts of iron, copper, lead, &c., may be prepared. A *methyl* salt is obtained by heating the silver salt with methyl iodide. When pure, it crystallises from boiling water in small, white needles which melt at 133—136°, and turn red when exposed to the air. No bromine derivative of either the acid or the methyl salt has hitherto been isolated. S. B. A. A.

Betaïnes of Pyridine Bases. By M. KRÜGER (*Ber.*, **23**, 2608—2610).—Chloracetic acid combines with pyridine, β-picoline, and ethylpiperidine at 100°, yielding the corresponding betaine hydrochloride; ethyl chloracetate combines with the above-named bases at the ordinary temperature, the chlorides of the betaïne ethyl salts being formed.

The hydrochlorides of the betaines are hygroscopic, crystallise well, and are readily soluble in hot alcohol, but insoluble in ether; the chlorides of the ethyl salts are also very hygroscopic. Both classes of compounds form platinochlorides, &c., and are converted into the betaïnes by moist silver oxide; the free betaïnes readily lose 1 mol. H_2O, yielding the inner anhydrides.

Pyridinebetaine, $C_7H_7NO_2 + H_2O$, forms a crystalline hydrobromide, nitrate, sulphate, and picrate, as well as a basic hydrochloride of the composition $2C_7H_7NO_2,HCl + H_2O$; with chromic acid, it yields the compound $C_7H_7NO_2,CrO_3$, and with silver nitrate, the compound $C_7H_7NO_2,AgNO_3$. It combines with potassium bismuthoiodide to form a bright-red, crystalline salt of the composition $C_7H_7NO_2,HBiI_4 + 2H_2O$, and when heated with bromine at 100°, it yields pyridinebetaïne hydrobromide. When oxidised with potassium permanganate and when distilled, it is converted into pyridine, but on reduction with sodium amalgam, it yields a base, the platinochloride of which has probably the composition $(C_7H_{11}NO)_2,H_2PtCl_6$. F. S. K.

Action of Methyl Iodide on Pentamethyldihydropyridine. By F. ANDERLINI (*Gazzetta*, **20**, 61—64).—Unlike most tertiary bases which combine with 1 mol. of methyl iodide yielding the iodide of a compound ammonium, pentamethyldihydropyridine reacts with 2 mols. of methyl iodide forming the hydriodide of a new base, $C_{12}H_{21}N$.

The hydriodide is obtained in the form of a brown syrup, and cannot be directly analysed; it may be converted into the hydrochloride by decomposing its aqueous solution with silver chloride; the hydrochloride gives no precipitate with platinic chloride, but it yields an oily *picrate* and an *aurochloride*, $C_{12}H_{21}N,HAuCl_4$, which crystallises in needles and melts at 99·5—100·5°. On treating the aqueous solution of the hydriodide with caustic potash and steam-distilling the oily product, an easily oxidisable oil with a penetrating odour passes over; this yields a deliquescent uncrystallisable hydrochloride, from which an oily picrate and an aurochloride identical with that described may be obtained. If the new base is in reality a pyridine derivative, as appears probable, it would necessarily have the constitution of a *heptamethyldihydropyridine*. S. B. A. A.

The Second β-Picoline, and the Constitution of Pyridine and Benzene. By A. LADENBURG (*Ber.*, 23, 2688—2693).—It has previously been pointed out (*Ber.*, 23, 1010) that the β-picoline obtained by Hesekiel from glycerol differs in certain particulars from that obtained by Stöhr from strychnine, and the author has therefore re-examined the compounds from both sources with great care, and finds that they are in fact not identical. The base obtained from strychnine is termed β′-picoline in the sequel.

In agreement with previous determinations, the boiling point of β-picoline was found to be 141 5—142° (uncorr.), and β′-picoline 146—149·5° (uncorr.), and the melting points of the mercury double salts to be 145—146° and 139—140° respectively.

There is also a very marked difference in their behaviour when mixed with water. When the latter is added drop by drop to β-picoline, no cloudiness is observed under any conditions; with β′-picoline, however, a separation of an oily layer soon takes place, which disappears on shaking so long as the quantity of water is small and the temperature low. A mixture of 1 vol. of the base with 3 vols. of water is most susceptible to slight changes of temperature, the warmth of the hand being sufficient to cause an immediate precipitation, and in the summer the liquid separates completely into two distinct layers. Moreover, the platinochlorides of both bases readily pass into the corresponding platinous chlorides on boiling with water, which are also not identical with one another, the β-picoline salt melting at 240—241°, and that of β′-picoline at 256—258°.

There can therefore be no doubt that two isomeric β-picolines exist, and it is also probable that the same is true of nicotinic acid, α-picoline, and α-picolinic acid. As regards α-picoline, it may be mentioned that the compound obtained by Weidel from bone oil (Abstr., 1880, 268) differs in certain respects from that obtained synthetically by Ladenburg and Lange (*Annalen*, 247, 6). If this difference is confirmed, the existence of five isomeric monosubstituted picolines will have been proved, which in turn will be a final proof of the Korner-Dewar formula of pyridine.

The author also believes that the existence of two isomeric β-picolines of this constitution shows that Kekulé's formula really demands the existence of five isomeric disubstitution products of benzene, and that the prism formula is the only one which satisfies the laws of subtitution. This formula does not, however, account for all the relationships of benzene, and it will therefore be necessary to retain the hexagonal formula along with the prism formula. H. G. C.

Formation of Lepidine Derivatives from Chinine and Cinchine. By W. KOENIGS (*Ber.*, 23, 2669—2679).—When chinine, obtained by Comstock and Koenigs from quinine (Abstr., 1887, 281, 1122), is allowed to remain for 14 days with hydrobromic acid, saturated at −17°, 1 mol. of methyl bromide is formed, and *hydrobromoxycinchine hydrobromide*, $C_{19}H_{21}BrN_2O,2HBr$, separates out. The free base is obtained by the action of ammonium carbonate, and purified by recrystallisation from alcohol. It is sparingly soluble in alcohol, but dissolves more readily in chloroform, and melts indefinitely at 180—190°. Its *sulphate* crystallises in slender, yellow, concentrically grouped needles. When boiled with alcoholic potash, it is converted into the corresponding *oxycinchine*, $C_{19}H_{20}N_2O$, which is purified by conversion into the tartrate, the latter being sparingly soluble in cold water. Oxycinchine is a yellowish, amorphous compound which melts at 100—110°, is readily soluble in methyl and ethyl alcohol, acetone, and chloroform, but could not be obtained crystalline. The salts are for the most part readily soluble, and the *hydrochloride* may be crystallised from absolute alcohol. The *platinochloride*, $C_{19}H_{20}N_2O,H_2PtCl_6$, crystallises from hot, dilute hydrochloric acid in yellow, sparingly soluble plates.

On continued boiling with concentrated hydrobromic acid, oxycinchene, like chinine, is converted into apocinchene, $C_{19}H_{19}NO_2$. If, however, it be heated with ammonio-zinc chloride and ammonium chloride, in the manner described by Merz and Müller (Abstr., 1887, 243), a totally different reaction takes place, *paramidolepidine*, $C_9NH_5Me{\cdot}NH_2$, being formed. This is separated from the product of the reaction by extraction with water and dilute soda solution, which is in turn extracted with ether. The crude base remaining on evaporation is purified by conversion into the crystalline acid tartrate, decomposing the latter with sodium carbonate, and crystallising from hot water. Paramidolepidine is thus obtained in beautiful, colourless needles which melt at 168—170°, and are readily soluble in alcohol and chloroform, but somewhat more sparingly in ether and hot water. It dissolves in dilute mineral acids with a yellow colour, which disappears with an excess of acid. the solutions showing a green fluorescence. When treated with sodium nitrite and an alkaline solution of stannous chloride, it yields a compound corresponding in its properties to lepidine.

When the zinc soluble salt of chinine (Abstr., 1887, 281) is heated with water at 190—200° under pressure, it yields, besides resinous matters, *paramethoxylepidine*, $C_9NH_5Me{\cdot}OMe$, which is purified by successive conversion into the acid tartrate and the sulphate The. free base, obtained from the latter by treatment with alkalis, crystallises from dilute alcohol in slender, colourless needles, and melts at 50—51°. It gives the quinine reaction with chlorine-water and ammonia, the coloration being, however, of a greenish-blue tint, and the solution, if not too dilute, yields after a time a precipitate resembling Prussian blue. The *zincochloride* crystallises in small colourless needles melting at 245° with decomposition, and the *platinochloride*, $(C_{11}H_{11}NO)_2,H_2PtCl_6$, forms an orange-yellow, crystalline powder, very sparingly soluble in hot water, and melting at 236—237° with decomposition. In addition to paramethoxylepidine, a compound is also formed in the above reaction which appears to be identical with the parahydroxylepidine described below. Paramethoxylepidine is among the products of the action of potash on quinine and the allied alkaloïds (compare Krakau, Abstr., 1885, 1081).

Parahydroxylepidine, $C_9NH_5Me{\cdot}OH$, is obtained by heating paramethoxylepidine with concentrated hydrobromic acid. The diluted acid solution is treated with an excess of sodium carbonate, the precipitate dissolved in caustic soda solution, reprecipitated by carbonic anhydride, and crystallised from 50 per cent. alcohol. It forms colourless needles which melt and become brown at 216—218°, and are sparingly soluble in hot water; the solution does not give any characteristic colour reaction with ferric chloride. The *hydrogen tartrate* also crystallises well.

When cinchene is heated with water and acetic acid at 200° for 10 hours, it behaves in a similar manner to chinine, and is converted into lepidine. Quinine and cinchonine, on the other hand, under the same conditions only yield traces of methoxylepidine or lepidine, whilst benzylidinelepidine, $C_9NH_6{\cdot}CH{:}CHPh$, is readily split up into lepidine and benzaldehyde. It is possible therefore that in chinine and cinchene, the carbon atoms next to the quinoline ring are also doubly linked, and that in quinine and cinchonine a hydrogen atom and a hydroxyl group are combined with these atoms. This is not, however, sufficient by itself to explain the formation of apochinine and apocinchene (*loc. cit.*), or to explain the fact that the latter are so much more stable than the compounds from which they are obtained.

H. G. C.

Substitution Products of Lepidine. By A. Busch and W. Koenigs (*Ber.*, **23**, 2679—2688).—In view of the results mentioned in the previous abstract, it appeared desirable to obtain para-derivatives of lepidine directly from the base itself. From the results of Weidel (Abstr., 1882, 225) and Georgievics (Abstr., 1888, 501), it appeared most probable that such compounds would be obtained by the sulphonation of lepidine at a high temperature, and it was found that the parasulphonic acid can in fact be thus readily prepared. In carrying out the reaction, lepidine (2 grams) is mixed with eight times the quantity of pure sulphuric acid, cooling during the addition, and then heated for half an hour at 300°, and poured, on cooling, into 10—15 times the volume of absolute alcohol. The separated sulphonic acid crystallises from hot water in almost colourless, silky needles, having the composition $C_9NH_5Me{\cdot}SO_3H + H_2O$, the water of crystallisation being given off at 100°. The *silver* salt crystallises in slender, colourless needles, also containing 1 mol. of water of crystallisation, which is given off at 140°, the residue assuming a reddish coloration; the *mercuric* salt is a crystalline precipitate. The acid is quite different from the lepidinesulphonic acid described by Weidel and Hazura (Abstr., 1885, 562).

As the parasulphonic acid is only slightly attacked by chromic acid, it was first converted into the *benzylidene* compound,

$$SO_3H \cdot C_9NH_5 \cdot CH{:}CHPh,$$

by heating with benzaldehyde, zinc chloride, and a little water. This forms sulphur-yellow crystals containing 2 mols. of water of crystallisation, which are given off at 180°, the sulphur-yellow colour changing to orange. To carry out the oxidation, this compound is dissolved in the requisite quantity of soda solution, and a 1 per cent. solution of potassium permanganate added, until it is no longer decolorised on standing. The solution is then boiled, decolorised with a little sodium hydrogen sulphite, filtered, and acidified with nitric acid. The crystals which separate on cooling are extracted with alcohol and ether to remove benzoic acid, and recrystallised from water. *Sulphocinchonic acid*, $C_{10}H_7NSO_5 + H_2O$, is thus obtained in fascicular aggregates of lustrous, colourless needles, containing 1 mol. H_2O. It dissolves readily in hot, less easily in cold water, and still less in alcohol, and bears the strongest resemblance to the β-sulphocinchonic acid obtained by Weidel and Georgievics (*loc. cit.*) from α-cinchonic acid. On fusion with potash, it yields a β-hydroxycinchonic acid identical with Skraup's xanthochinic acid, and is therefore probably a para-compound. This assumption is also supported by the fact that quinoline, by sulphonation under similar circumstances, yields an undoubted para-derivative. The acid obtained by Weidel differed from the acid from benzylidinelepidinesulphonic acid, inasmuch as it contained 2 mols. H_2O; but cinchonic acid itself crystallises sometimes with 1 mol. and sometimes with 2 mols. H_2O.

Parahydroxylepidine, $C_9NH_5Me \cdot OH$, is obtained from the sulphonic acid by fusion with soda and a little water in the usual manner. It crystallises from hot water, after treatment with animal charcoal, in colourless, fascicular aggregates of needles melting and becoming brown at 216—218°, and identical with the compound obtained from chinine (see preceding abstract). The corresponding *paramidolepidine*, $C_9NH_5Me \cdot NH_2$, prepared from the hydroxy-compound by heating it with ammonio-zinc chloride, is also identical with the compound there described.

When lepidine and sulphuric acid are mixed without cooling, and slowly heated to 300°, a sulphonic acid is obtained which appears to consist of a mixture of the above lepidineparasulphonic acid with an isomeric acid, probably the ortho-compound. When the mixture is fused with 6 parts of potash and 6 parts of soda, the melt acidified with sulphuric acid, made slightly alkaline, and distilled in a current of steam, it yields a greenish, crystalline compound with a peculiar odour melting at 141°. It probably consists of *orthohydroxylepidine*, and yields a *platinochloride*, $(C_{10}H_9NO)_2,H_2PtCl_6$, crystallising in orange-yellow needles.

Ortho- (?) nitrolepidine is prepared by mixing 1 part of lepidine with 1 part of sulphuric acid, and adding, first, 5 parts of colourless

5 *d* 2

fuming nitric acid of sp. gr. 1·525, and then 5 parts of sulphuric acid, and allowing the mixture to remain for 12 hours; the liquid is then poured into water, soda added, and the solution extracted with benzene. The oily residue obtained on evaporating the latter is treated with light petroleum, and the brown crystals thus formed repeatedly crystallised from absolute alcohol. It forms lustrous, almost colourless needles melting at 126—127°, and sparingly soluble in cold alcohol. Nitroquinoline is best prepared in a similar manner from quinoline.

H. G. C.

α-Picolylethylalkine and its Derivatives. By A. MATZDORFF (*Ber.*, **23**, 2709—2713).—α-Picoline and propaldehyde unite together in presence of water when heated at 160—170° under pressure, forming *α-picolylethylalkine*, $C_5NH_4\cdot CH_2\cdot CHEt\cdot OH$. The product is made alkaline, distilled in a current of steam, acidified, and extracted with chloroform, again made alkaline, and re-extracted with chloroform. The second extract leaves the α-picolylethylalkine on evaporation as a reddish-brown oil, which is purified by distillation in a vacuum. It forms a colourless oil which boils at 125—127° (18 mm.), is readily soluble in water, alcohol, and chloroform, and becomes yellow in the air. It can only be dried by means of potassium carbonate, as water is readily split off if potassium hydroxide is used. The *platinochloride*, $(C_9H_{13}NO)_2,H_2PtCl_6$, forms cubical crystals which melt at 154° with decomposition, and the *aurochloride*, $C_9H_{13}NO,HAuCl_4$, crystallises in long needles melting at 97·5—99°.

As mentioned above, α-picolylethylalkine loses water in contact with potash, the product formed being 2-crotylpyridine. In this manner it is, however, always obtained mixed with α-picoline, and it is better to prepare it by heating the alkine with concentrated hydrochloric acid at 160—170°, saturating with soda, and distilling in a current of steam. *Crotylpyridine*, $C_5NH_4\cdot CH\colon CHEt$, is a colourless, mobile liquid having a strong conyrine-like odour; it boils at 147—149° (75 mm.), and is readily soluble in alcohol, ether, and chloroform, but almost insoluble in water. Its *platinochloride*, $(C_9H_{11}N)_2,H_2PtCl_6$, crystallises in beautiful needles or plates melting at 140°, and its *aurochloride*, $C_9H_{11}N,HAuCl_4$, in small needles which blacken and melt at 127·5—130°.

On reduction with sodium in alcoholic solution, α-picolylethylalkine readily yields the corresponding *α-pipecolylethylalkine*,

$$C_5NH_{10}\cdot CH_2\cdot CHEt\cdot OH,$$

an almost colourless oil boiling at 242—243°, and readily soluble in water, alcohol, and ether. It does not yield salts. H. G. C.

Methylethylpyridylalkine. By G. PRAUSNITZ (*Ber.*, **23**, 2725—2726).—The collidine, C_5NH_3MeEt, prepared by heating aldehyde-ammonia with paraldehyde, was heated with formaldehyde and a 1½ per cent. soda solution in sealed tubes for 10—12 hours at 160—170°. The contents were then washed out with water and distilled with steam, and the *methylethylpyridylalkine*,

$$C_5NH_3Et\cdot CH_2\cdot CH_2\cdot OH,$$

extracted from the residue with chloroform. It is a pale yellow oil of sp. gr. 1·066 at 0°, and boils at 147—149° under 18 mm. pressure. It dissolves easily in water and alcohol, less easily in ether. The *platinochloride*, $2C_9H_{13}NO,H_2PtCl_6$, forms red, cubical crystals which melt at 159° with effervescence. The *aurochloride* forms brilliant, yellow plates, the *picrate* small, very soluble prisms. The cadmio-iodide is an oil. C. F. B.

α-Picolylfurylalkine and α-Pipecolylfurylalkine. By O. Klein (*Ber.*, **23**, 2693—2696).—Furfuraldehyde combines with α-picoline when mixed with a little water and heated at 140—150° under pressure for 8—9 hours, no elimination of water taking place. The product is distilled in a current of steam to remove hydrocarbons and unaltered α-picoline and furfuraldehyde, the residue extracted with chloroform and, after evaporation of the latter, distilled under diminished pressure. The base passes over at 164° under 20 mm. pressure as a greenish liquid, which solidifies to a hard yellow cake. On analysis it gave numbers agreeing with the formula $C_{11}H_{11}NO_2$, and it is therefore *α-picolylfurylalkine*, $C_5NH_4{\cdot}CH_2{\cdot}CH(OH){\cdot}C_4OH_3$. It has a characteristic, not unpleasant, odour, and is readily soluble in alcohol, ether, and chloroform, insoluble in water, and melts at 41—43°. Its *platinochloride*, $(C_{11}H_{11}NO_2)_2,H_2PtCl_6$, forms brownish-yellow, fascicular aggregates of crystals melting at 160—162° with decomposition; the *mercurochloride*, $C_{11}H_{11}NO_2,HHgCl_3$, crystallises in beautiful, iridescent needles melting at 147—150°, the *cadmio-iodide*, $C_{11}H_{11}NO_2,HCdI_3$, in yellowish-red plates, and the *picrate*, $C_{11}H_{11}NO_2,C_6H_3N_3O_7$, in yellow needles melting at 157—160°.

When α-picolylfurylalkine is treated with benzoic anhydride, it forms *benzoylpicolylfurylalkeine*, $C_{11}H_{10}BzNO_2$, which crystallises in brown, fascicular aggregates and melts at 47—49°. Its *platinochloride*, $(C_{11}H_{10}BzNO_2)_2,H_2PtCl_6$, forms small, brown needles melting at 140—145° with decomposition, and its *mercurochloride*,

$$C_{11}H_{10}BzNO_2,HHgCl_3,$$

crystallises from dilute hydrochloric acid in pale yellow needles. The corresponding *acetyl* derivative, $C_{11}H_{10}AcNO_2$, could only be obtained as a dark brown oil, but its *platinochloride*, $(C_{11}H_{10}AcNO_2)_2,H_2PtCl_6$, crystallises from water containing hydrochloric acid in brownish needles melting at 163—165°, and its *mercurochloride*,

$$C_{11}H_{10}AcNO_2,HHgCl_3,$$

in small, yellow needles melting at 152—155° with decomposition.

On reduction with sodium in alcoholic solution, α-picolylfurylalkine is converted into the corresponding hydro-base, *α-pipecolylfurylalkine*. This is a yellowish oil boiling at 248—251° (760 mm.), and 118—123° (15 mm.). It gradually becomes of a darker colour, and does not yield crystalline salts. H. G. C.

Metanitro-α-stilbazole, its Reduction Products, and Anisilidenepyridylalkine. By A. Schuftan (*Ber.*, **23**, 2716—2719).—Metanitrobenzaldehyde was treated with picoline, the mixture acidified, diluted with water, extracted with ether, and finally decomposed with potash. *Metanitro-α-stilbazole*, $NO_2\cdot C_6H_4\cdot CH:CH\cdot C_5NH_4$, then separated in brown flakes which, when purified with animal charcoal and recrystallised from alcohol, formed shining, white plates melting at 120°, dissolving easily in alcohol, ether, chloroform, and carbon bisulphide, sparingly in hot, and not at all in cold water; its solution is neutral. The *platinochloride*, $2C_{13}H_{10}N_2O_2,H_2PtCl_6$, forms yellow needles melting with decomposition at 240°. The *mercurochloride*, $C_{13}H_{10}N_2O_2,HHgCl_3$, crystallises in groups of yellowish needles melting at 211° with decomposition. The *picrate* forms brilliant, golden-yellow plates which blacken when heated. The substance also yields a bromine additive product which crystallises from alcohol in white needles melting at 145°.

When the nitro-compound is reduced with tin and hydrochloric acid, it yields *metamido-α-stilbazole*, $NH_2\cdot C_6H_4\cdot CH:CH\cdot C_5NH_4$, which crystallises from dilute alcohol in yellowish needles melting at 85°, and when dried in a vacuum has the composition $C_{13}H_{12}N_2,\frac{1}{2}H_2O$. It is a di-acid base with an alkaline reaction, and dissolves sparingly in water, easily in alcohol, ether, and chloroform. The *platinochloride*, $2C_{13}H_{12}N_2,H_2PtCl_6,H_2O$, forms groups of very soluble, reddish-yellow needles which blacken when heated. The *mercurochloride* forms groups of white needles very soluble in water. A bromine additive product was also obtained.

When the original nitro-compound is reduced with sodium and absolute alcohol, *metamido-α-stilbazoline*, $NH_2\cdot C_6H_4\cdot CH_2\cdot CH_2\cdot C_5NH_{10}$, is obtained as a strongly alkaline, yellow oil boiling above 360° under atmospheric pressure, and at 200—205° under 25 mm. It smells like piperidine, gives the nitroso-reaction for the imido-group, and dissolves in alcohol, ether, chloroform, and hot water. Its *platinochloride* forms very unstable, yellow plates. No other crystalline salts could be obtained.

By treating picoline with anisaldehyde, *anisilidenepyridylalkine*, $OMe\cdot C_6H_4\cdot CH:CH\cdot C_5NH_4$, was obtained in brilliant, white, cetaceous plates, melting at 97°, soluble in ether and chloroform, and sparingly in hot water.

The *platinochloride*, $2C_{14}H_{13}NO,H_2PtCl_6$, forms yellow plates melting at 184°.

C. F. B.

Hydroxy-α-stilbazole and its Derivatives. By F. Butter (*Ber.*, 23, 2697—2700).—When α-picoline (10 grams), salicylaldehyde (13 grams), and water (7 grams) are heated in a sealed tube at 140°, the first two compounds unite together directly. The product is treated with hydrochloric acid, extracted with ether, made alkaline, and distilled in a current of steam. The residue on cooling deposits the crude base as a brown, solid mass, which is recrystallised from dilute alcohol and finally from water. It is thus obtained as an almost white, crystalline compound sparingly soluble even in hot water, readily in alcohol and ether. Analysis confirmed the formula $C_{13}H_{11}NO$, and it is therefore from its mode of formation *hydroxy-α-stilbazole*, $C_5NH_4\cdot CH:CH\cdot C_6H_4\cdot OH$. It is neutral towards litmus, but dissolves in acids and also in soda. Its *platinochloride*,

$(C_{13}H_{11}NO)_2, H_2PtCl_6$, forms dull, reddish-brown needles which melt at 187—188° with decomposition, and its *mercurochloride* forms radial, eccentric groups of needles melting at 167—170°.

When hydroxy-α-stilbazole (3 grams) is treated with soda (0·7 gram) and ethyl iodide (2·3 grams) in aqueous solution, it is converted into *ethoxy-α-stilbazole*, $C_5NH_4 \cdot CH{:}CH \cdot C_6H_4 \cdot OEt$. This is a yellow, non-crystallisable oil, which yields a *platinochloride*, $(C_{15}H_{15}NO)_2,H_2PtCl_6$, as a reddish-yellow, crystalline powder melting at 181—183°, and a *mercurochloride*, $(C_{15}H_{15}NO)_2,HHgCl_3$, crystallising in pale yellow needles which melt at 91—92°. If double the quantity of ethyl iodide given above be taken, *ethoxy-α-stilbazole ethiodide* $C_5NH_4 \cdot CH{:}CH \cdot C_6H_4 \cdot OEt,EtI$, is formed, and crystallises from hot dilute alcohol in golden-yellow, transparent crystals melting at 217·5°.

Hydroxy-α-stilbazole is acted on by bromine-water in hydrochloric acid solution, the *dibromide*, $C_5NH_4 \cdot CHBr \cdot CHBr \cdot C_6H_4 \cdot OH$, being formed as an oil which solidifies to yellow, crystalline flocks. On reduction with sodium in alcoholic solution, hydroxy-α-stilbazole is converted into *hydroxy-α-stilbazoline*, $C_5NH_{10} \cdot CH_2 \cdot CH_2 \cdot C_6H_4 \cdot OH$, crystallising from light petroleum in white, arborescent aggregates of crystals which melt at 93—94°, and do not yield crystalline salts.

H. G. C.

Derivatives of β-Pyrazole. By MAQUENNE (*Compt. rend.*, **111**, 113—116).—An aqueous solution of nitrotartaric acid is mixed with a corresponding quantity of aldehyde and an excess of ammonia. Heat is developed, and after some time a crystalline mass of ammonium β-pyrazole-4 : 5-dicarboxylate separates. The free acid is obtained by saturating the cold ammoniacal liquid with hydrochloric acid; nitrogen oxides are evolved, and hence nitrotartaric acid has behaved towards the alkali as if it were the symmetrical dinitrous ether of dihydroxytartaric acid. If a mixture of sodium dihydroxytartrate and aldehyde is boiled with excess of ammonia, the slightly soluble sodium salt of the same pyrazolecarboxylic acid separates, and hence it is clear that in the reaction first mentioned the nitrotartaric acid is first converted into dihydroxytartaric acid and ammonium nitrite.

β-Pyrazole-4 : 5-dicarboxylic acid (glyoxalinedicarboxylic acid). $C_3N_2H_2(COOH)_2$, is obtained from formaldehyde in ammoniacal solution, and forms a white powder consisting of slender needles or microscopic octahedra. It is almost insoluble in water, and its salts with the alkalis and alkaline earths, although crystallisable, are only slightly soluble. The other salts are generally amorphous; only the mono-metallic salts are well-defined. Dry distillation converts the acid completely into β-pyrazole (glyoxaline).

2-Methyl-β-pyrazole-4 : 5-dicarboxylic acid, $C_3N_2HMe(COOH)_2 + H_2O$, is obtained easily from ordinary aldehyde. It is only slightly soluble, even in boiling water, but crystallises in brilliant, white needles, which begin to lose water at about 130°, but only become anhydrous at 170°. The mono-metallic salts of the alkalis and alkaline earths are only slightly soluble, but crystallise readily in anhydrous crystals. When heated, the acid yields glyoxalethyline and carbonic anhydride.

Isobutylglyoxalinedicarboxylic acid and *phenylglyoxalinedicarboxylic acid* are obtained in a similar manner, and the reaction seems to be general for primary aldehydes of simple function. Although the constitution of these acids shows that they should be bibasic, they form only mono-metallic salts. At the same time, the acids form neither hydrochlorides nor platinochlorides, and hence it would seem that the strongly basic pyrazole nucleus saturates one of the acid functions.

C. H. B.

Constitution of Carbizines. By M. Freund and F. Kuh (*Ber.*, 23, 2821—2844).—Freund and Goldsmith have described (Abstr., 1888, 1187) a series of compounds, prepared by the action of carbonyl chloride on acid derivatives of phenylhydrazine, which they regarded as derivatives of the hypothetical carbizine group  $\mathrm{CO}<\begin{matrix}\mathrm{NH}\\ |\\ \mathrm{NH}\end{matrix}$. The corresponding sulphur compounds, prepared by E. Fischer and Besthorn (compare Abstr., 1888, 1091), by heating phenylthiosemicarbazide, were believed to have the formula  $\mathrm{NPh}<\begin{matrix}\mathrm{N}\\ \|\\ \mathrm{C{\cdot}SH}\end{matrix}$, since they are isomeric with the substances obtained by the action of thiocarbonyl chloride on acid phenylhydrazine derivatives. It is found, however, that diphenylcarbazide only reacts with 1 mol. of carbonyl chloride or thiocarbonyl chloride, instead of 2 mols. as would be expected from the constitution of the carbizines. Only one of the oxygen atoms of acetylphenylcarbazide reacts with phosphorus pentachloride. Contrary to expectation, carbonyl chloride has no action on certain compounds, the atoms of which are not linked in a ring. These results all point to the conclusion that acid derivatives of phenylhydrazine are tautomeric, and have the two forms

$$\mathrm{NHPh{\cdot}NH{\cdot}CO{\cdot}R} \text{ and } \mathrm{NHPh{\cdot}N{:}CR{\cdot}OH};$$

the compounds obtained by the action of carbonyl chloride and thiocarbonyl chloride are derived from the second form, and consequently contain the complex  $\begin{matrix}\mathrm{NH{\cdot}N}\\ |\\ [\mathrm{S}]\,\mathrm{CO{\cdot}O}\end{matrix}>\mathrm{CR}$. It is proposed to term the groups  $\mathrm{O}<\begin{matrix}\mathrm{CH_2{\cdot}NH}\\ |\\ \mathrm{CH{:}N}\end{matrix}$ and  $\mathrm{O}<\begin{matrix}\mathrm{CO{\cdot}NH}\\ |\quad |\\ \mathrm{CH{:}N}\end{matrix}$ biazoline and biazolone respectively; the corresponding sulphur compounds,

$$\mathrm{S}<\begin{matrix}\mathrm{CO{\cdot}NH}\\ |\\ \mathrm{CH{:}N}\end{matrix},\ \mathrm{O}<\begin{matrix}\mathrm{CS{\cdot}NH}\\ |\\ \mathrm{CH{:}N}\end{matrix},\ \text{and } \mathrm{S}<\begin{matrix}\mathrm{CS{\cdot}NH}\\ |\\ \mathrm{CH{:}N}\end{matrix},$$

being called thiobiazolone, ψ-thiobiazolone, and dithiobiazolone.

Phenylazophenylthiobiazolone,  $\begin{matrix}\mathrm{NPh{\cdot}N}\\ |\\ \mathrm{CO-S}\end{matrix}>\mathrm{C{\cdot}N_2Ph}$, is prepared by the action of carbonyl chloride on diphenylthiocarbazide; it crystallises from alcohol in stellate groups of golden needles melting at 140°, and is insoluble in water, but readily dissolves in ether, benzene, or chloroform. This compound is derived, in all probability, from the tautomeric form of the carbazide $\text{NHPh}\cdot\text{N}:\text{C(SH)}\cdot\text{NH}\cdot\text{NHPh}$; it may also be obtained by the action of carbonyl chloride on the blue dye $\text{NPh}:\text{N}\cdot\text{CS}\cdot\text{NH}\cdot\text{NHPh}$, which is formed by the oxidation of diphenylthiocarbazide.

Phenylhydrazophenylthiobiazolone,  $\begin{array}{l}\text{NPh}\cdot\text{N}\\ |\\ \text{CO}-\text{S}\end{array}\!\!>\text{C}\cdot\text{NH}\cdot\text{NHPh}$, is obtained by the reduction of the previous compound with hydrogen sulphide; it crystallises from alcohol in small, white, interlaced needles melting at 124°, and is more readily soluble in ether or alcohol than the azo-derivative. By the action of oxidising agents, or of carbonyl chloride, the azo-compound is regenerated. Experiments with thiocarbonyl chloride on diphenylsulphocarbazide were unsuccessful.

Phenylazophenyldithiobiazolone,  $\begin{array}{l}\text{NPh}\cdot\text{N}\\ |\\ \text{CS}-\text{S}\end{array}\!\!>\text{C}\cdot\text{N}_2\text{Ph}$, is prepared by the action of thiocarbonyl chloride on the above blue compound; it is deposited from benzene in dark-red crystals which melt at 160—165° with partial decomposition, and are readily soluble in alcohol, ether, chloroform, and glacial acetic acid, but more sparingly in benzene or light petroleum. On reduction with hydrogen sulphide, *phenylhydrazophenyldithiobiazolone*,  $\begin{array}{l}\text{NPh}\cdot\text{N}\\ |\\ \text{CS}-\text{S}\end{array}\!\!>\text{C}\cdot\text{NH}\cdot\text{NHPh}$, is formed, crystallising in brown plates which melt at 142°, and are sparingly soluble in alcohol, but more readily in ether, benzene, or light petroleum.

Phenylhydrazophenylbiazolone,  $\begin{array}{l}\text{NPh}\cdot\text{N}\\ |\\ \text{CO}-\text{O}\end{array}\!\!>\text{C}\cdot\text{NH}\cdot\text{NHPh}$, is prepared by heating diphenylcarbazide with carbonyl chloride in a sealed tube at 160°; it is deposited from alcohol or glacial acetic acid in white crystals which melt at 180—181°, and are insoluble in benzene and toluene, but soluble in ether or chloroform. On oxidation with ferric chloride, *phenylazophenylbiazolone*,  $\begin{array}{l}\text{NPh}\cdot\text{N}\\ |\\ \text{CO}-\text{O}\end{array}\!\!>\text{C}\cdot\text{N}_2\text{Ph}$, is formed, crystallising from alcohol in small, yellow plates melting at 198—200°. By the action of tin and hydrochloric acid on phenylhydrazophenylbiazolone, aniline is eliminated, and *phenylamidobiazolone* (*amidophenylcarbizincarboxylic acid*),  $\begin{array}{l}\text{NPh}\cdot\text{N}\\ |\\ \text{CO}-\text{O}\end{array}\!\!>\text{C}\cdot\text{NH}_2$, is formed.

Phenylazophenyl-ψ-thiobiazolone,  $\begin{array}{l}\text{NPh}\cdot\text{N}\\ |\\ \text{CS}-\text{O}\end{array}\!\!>\text{C}\cdot\text{N}_2\text{Ph}$, is prepared by the action of thiocarbonyl chloride on diphenylcarbazine at 450°; it is deposited from glacial acetic acid in clusters of yellowish-red crystals melting at 170° with partial decomposition, and is readily soluble in all the ordinary media except water.

Phenylmethyldichlorobiazolone,  $\begin{array}{l}\text{NPh}\cdot\text{N}\\ |\\ \text{CCl}_2\cdot\text{O}\end{array}\!\!>\text{CMe}$, is prepared by heating a mixture of phosphorus pentachloride and phenylmethylbiazolone (acetylphenylcarbizine) in molecular proportion at 150°; it crystallises from anhydrous ether in stellate groups of small, white needles which melt at 120—122°, and are readily soluble in benzene, chloroform, or light petroleum. The compound is slowly decomposed by water at ordinary temperatures, the biazolone being regenerated. Phenylmethyl-ψ-thiobiazolone is formed by the action of hydrogen sulphide on the dichloride; it has been previously prepared by treating acetylphenylhydrazine with thiocarbonyl chloride. All attempts to prepare phenylmethyltetrachlorobiazolone were fruitless. Phenylthiocarbamide is formed by the action of phosphorus pentasulphide on phenylmethylbiazolone.

Phenylmethylimidobiazole,  $\mathrm{CMe}<\begin{array}{l}\mathrm{N\cdot NPh}\\ \quad\;|\\ \mathrm{O\cdot C{:}NH}\end{array}$, is obtained by heating the chlorinated derivative with alcoholic ammonia in a sealed tube for 3—4 hours at 150°; it crystallises from alcohol in small, white needles melting at 112°, and is readily soluble in ether, benzene, or light petroleum; the biazolone is regenerated on treatment with water. The compound could not be obtained by the direct action of ammonia on the biazolone. *Phenylmethylbiazoline*,  $\begin{array}{l}\mathrm{NPh\cdot N}\\ |\\ \mathrm{CH_2\cdot O}\end{array}>\mathrm{CMe}$, prepared by the reduction of the chloro-compound with zinc and hydrochloric acid, after repeated recrystallisations from alcohol, is deposited in slightly yellow plates melting at 140°.

Paradichlorohydrazobenzene may readily be obtained from paradichlorazobenzene by reduction in alcoholic solution; no derivative of carbonyl chloride could be prepared, the compound being either recovered unaltered, or else completely decomposed, according to the experimental conditions. Similar results were observed with hydrazotoluene, and also with the three compounds obtained by Fries by the action of phenylhydrazine on cyanuric chloride. J. B. T.

Quinazolines. By S. Gabriel and R. Jansen (*Ber.*, 23, 2807—2814). —*Orthonitrobenzylbenzamide*, $NO_2\cdot C_6H_4\cdot CH_2\cdot NHBz$, is prepared by treating an aqueous solution of orthonitrobenzylamine hydrochloride (1 mol.) with sodium hydroxide (2 mols.) and benzene chloride (1 mol.); after some time, the oil which forms solidifies, and on recrystallisation from alcohol the compound is deposited in colourless needles melting at 110—112°. *Orthoamidobenzylbenzamide*, $NH_2\cdot C_6H_4\cdot CH_2\cdot NHBz$, is formed by the reduction of the nitro-compound with alcoholic hydrochloric acid and zinc; the product is treated with excess of sodium hydroxide, and extracted with ether; the residue remaining after evaporation of the ether crystallises from benzene in needles which melt at 108—109° (180—190° ?). It is readily soluble in ether, alcohol, chloroform, and dilute acids. On distillation, it yields benzonitrile, orthotoluidine, water, and *phenylquinazoline*,  $C_6H_4<\begin{array}{l}\mathrm{CH{:}N}\\ \mathrm{N{:}CPh}\end{array}>$, which boils above 300°, and crystallises from methyl alcohol in yellow, rhombic needles melting at 100—101°; it is a feeble base, and yields a colourless, crystalline *hydrochloride*.

Orthoamidobenzylacetamide, $NH_2\cdot C_6H_4\cdot CH_2\cdot NHAc$, is prepared from orthonitrobenzylacetamide by reduction with zinc and hydrochloric acid; it is readily soluble in ordinary menstrua, and crystallises from water in long needles melting at 112·5—113·5°. The *platinochloride* is crystalline. On distillation, water is eliminated, and above 300° *β-methyldihydroquinazoline*,  $C_6H_4<\begin{matrix}CH_2\cdot NH\\ |\\ N{=}CMe\end{matrix}$, passes over as a yellow, viscid liquid, which becomes colourless on purification; it is bitter to the taste, and the aqueous solution has an alkaline reaction. The *hydrochloride*, crystallises from methyl alcohol in short, colourless prisms which remain solid at 250°. The *picrate* is deposited from water in long needles which soften at about 180° and melt at 200°. The *dichromate* forms slender, reddish-yellow needles. The *platinochloride* is obtained in yellow needles.

Orthonitrobenzylformamide, $NO_2\cdot C_6H_4\cdot CH_2\cdot NH\cdot CHO$, is prepared by boiling orthonitrobenzylamine hydrochloride with anhydrous sodium formate and glacial formic acid for 1½ hours in a reflux apparatus; after treatment with water, the compound is deposited in compact aggregates of colourless, lustrous crystals melting at 88—90°. On reduction with zinc and hydrochloric acid, it yields *dihydroquinazoline*,  $C_6H_4<\begin{matrix}CH_2\cdot NH\\ |\\ N{=}CH\end{matrix}$, which is a yellow, viscid liquid; its aqueous solution has an alkaline reaction. The *hydrochloride* is deposited from absolute alcohol in small crystals. The *picrate* crystallises from absolute alcohol, and melts at about 215°, with previous softening at 200°. The *dichromate* and *platinochloride* are sparingly soluble, and crystalline.

J. B. T

Dihydroquinazolines. By C. PAAL and F. KRECKE (*Ber.*, 23, 2634—2641).—It has been shown by Paal and Busch (this vol., p. 71) that the formyl compounds of orthonitrobenzylaniline and of orthonitrobenzyl-ortho- and para-toluidine are converted, on reduction, into derivatives of quinazoline. The authors have, moreover, examined the action of reducing agents on orthonitrobenzylacetanilide, and find that in this case also a quinazoline derivative is readily formed.

Orthonitrobenzylacetanilide, $NO_2\cdot C_6H_4\cdot CH_2\cdot NAcPh$, is readily obtained by boiling orthonitrobenzylaniline for 1—2 hours with acetic anhydride (compare Lellman and Stickel, Abstr., 1886, 793). It forms large, transparent, yellowish crystals which melt at 75°, and are insoluble in water, sparingly soluble in light petroleum, but readily in the other common organic solvents. On reduction with tin and hydrochloric acid in alcoholic solution, it yields the stannochloride of *2-methyl-3-phenyldihydroquinazoline*,  $C_6H_4<\begin{matrix}N{=}CMe\\ |\\ CH_2\cdot NPh\end{matrix}$, which is converted into the *hydrochloride*, $C_{15}H_{14}N_2,HCl$, by treatment with hydrogen sulphide in dilute alcoholic solution. This forms colourless, transparent crystals containing 2 mols. H_2O, readily soluble in hot water and alcohol, which melt at 256—257°. The *platinochloride*, $C_{15}H_{14}N_2,H_2PtCl_6$, crystallises from hot alcohol in lustrous, flat, orange needles which decompose at 223°. To obtain the free base, the pure hydrochloride is decomposed with alkali, the separated oil extracted with ether, and the ethereal solution dried and evaporated. The residual oil gradually solidifies, and may then be recrystallised from benzene. It forms rosette-shaped groups of waxy needles which melt at 58—60°, and are insoluble in water, moderately soluble in light petroleum, and readily in other organic solvents and in mineral acids; with the latter it forms stable, well-crystallised salts.

When orthonitrobenzylaniline is reduced with tin and hydrochloric acid, it does not yield the corresponding orthamidobenzylaniline, but a base having the empirical formula $C_{13}H_{10}N_2$. It crystallises from hot alcohol in almost colourless needles melting at 81—83°, insoluble in water, sparingly soluble in light petroleum, readily in concentrated acids and organic solvents, and unlike orthoamidobenzylaniline it does not yield a quinazoline derivative when boiled with formic acid. Its *platinochloride* is a yellow, flocculent precipitate.

The above results agree well with those obtained by Lellmann and Stickel (*loc. cit.*), but not with those of Söderbaum and Widman (this vol., p. 1258). The latter investigators state that orthonitrobenzyltoluidine and orthonitrobenzanilide, on reduction, simply pass into the corresponding amido-compounds; and do not, as Lellmann and Stickel state, undergo condensation, forming a closed chain of carbon and nitrogen atoms. Possibly this discrepancy is due to the different methods of reduction employed. H. G. C.

Oxidation Products of Orthodiamines and Orthoamidophenols. By O. Fischer and E. Hepp (*Ber.*, **23**, 2787—2789; compare Abstr., this vol., p. 801).—The authors assigned the formula  $NH_2\!<\!\begin{smallmatrix}CH\cdot C\cdot N\\ \| \quad |\\ C_4H_4\cdot C\cdot N\end{smallmatrix}\!>\!C_6H_4$ to the eurhodine obtained from orthophenylenediamine and benzeneazo-*α*-naphthylamine; corresponding compounds have been prepared from orthophenylenediamine and benzeneazoethylnaphthylamine, and benzeneazodimethylnaphthylamine, respectively. The imide formula,  $NH{:}C\!<\!\begin{smallmatrix}CH : C\cdot NH\\ |\\ C_6H_4\cdot C{=}N\end{smallmatrix}\!>\!C_6H_4$, advanced by Kehrmann (this vol., p. 1266) for the above compound from benzeneazo-*α*-naphthylamine, is regarded by the authors as being a tautomeric form of their own. It is found that the action of amido-compounds on orthodiamines is not uniform; amidoazo-*α*-naphthylamine derivatives take part in the reaction, whilst amidoazobenzene derivatives chiefly act as dehydrogenating agents; thus diamidophenazine is obtained from orthophenylenediamine and amidoazobenzene, whilst triphenyldioxazine is formed by the action of orthoamidophenol on amidoazobenzene. J. B. T.

Fluorindine. By O. Fischer and E. Hepp (*Ber.*, **23**, 2789—2793; compare next abstract).—The term fluorindine is applied to a class of compounds formed by heating azophenine, or almost any induline base, and also by the action of orthophenylenediamine hydrochloride on diamidophenazine, the red oxidation product of orthophenylenediamine.

Fluorindine from Azophenine.—On heating azophenine alone, or with 2—3 parts of zinc-dust, *fluorindine* (*diphenylhomofluorindine*),  $C_6H_4\!<\!\begin{smallmatrix}NPh\\ \text{——}N\end{smallmatrix}\!\gg\!C_6H_2\!\ll\!\begin{smallmatrix}N\text{——}\\ NPh\end{smallmatrix}\!>\!C_6H_4$ [N : N = 2 : 3 : 5 : 6], is obtained,

in cantharidine-green needles; it may be recrystallised from naphthalene, or by treatment with a mixture of alcohol and benzene for a day in an extraction apparatus. It is almost insoluble in ether, toluene, and chloroform, and imparts a characteristic fluorescence to alcohol; the solution is flame-coloured in direct light, but on adding an acid, the colour changes to greenish-blue, with a brown-red fluorescence. No definite melting point could be observed, as the compound partially sublimes on heating; the colour of the vapour is blue-violet. The compound is not acted on by hydrochloric acid at 250°, and is only partially changed by concentrated hydriodic acid at 200°. Fluorindine is a feeble base, and consequently its dyeing powers are not well developed. On boiling with alcohol and an acid, the corresponding salt is obtained; most of the salts crystallise in bronze, lustrous plates, they readily undergo dissociation, and are insoluble in water, but dissolve sparingly in alcohol with a blue colour. The *aurochloride*, $C_{30}H_{20}N_4,HAuCl_4 + H_2O$, crystallises in iridescent, lustrous plates.

In the preparation of fluorindine by heating azophenine, a violet dye is formed as intermediate product; it is to be regarded as an *induline* with the formula  $C_6H_4{<}\genfrac{}{}{0pt}{}{NPh}{N}{>}C_6H_2(NHPh){:}NPh$.

FLUORINDINE FROM DIAMIDOPHENAZINE.—Diamidophenazine (4 parts) is intimately mixed with orthophenylaminediamine (3 parts), and heated in an oil-bath, first at 173°, then for 10—15 minutes at 200—210°; the product is boiled with water, and then with dilute sulphuric acid; a greenish powder remains, from which the free base is obtained by the action of alcoholic ammonia. The compound is very sparingly soluble in all menstrua, but by prolonged boiling with a mixture of alcohol and benzene it crystallises in slender, greenish, lustrous plates; it dissolves slightly in alcohol with a red-violet colour, and the solution exhibits an intense brownish-red fluorescence. The general properties of this substance resemble those of the previous base; it has the formula  $C_6H_4{<}\genfrac{}{}{0pt}{}{NH}{N}{>}C_6H_2{<}\genfrac{}{}{0pt}{}{N}{NH}{>}C_6H_4$, and it is proposed to term it *homofluorindine*. In all probability it is derived from the tautomeric form of diamidophenazine,  $C_6H_4{<}\genfrac{}{}{0pt}{}{NH}{N}{>}C_6H_2(NH_2){:}NH$. These results show that the fluorindines stand in the same relation to triphenodioxazine as phenazine does to phenoxazine. J. B. T.

Action of Quinones on Orthodiamines, Orthonitraniline, and Nitroparatoluidine. By J LEICESTER (*Ber.*, 23, 2793—2798; compare preceding abstract).—*Quinoneorthodinitranilide*,

$$C_6H_2O_2(NH{\cdot}C_6H_4{\cdot}NO_2)_2\ [O : NH : O : NH = 1 : 2 : 4 : 5],$$

is prepared by gently boiling quinone with orthonitraniline in glacial acetic acid solution; it crystallises from absolute alcohol in red needles melting at 305° with decomposition.

Quinonehomofluorindine,  $C_6H_4{<}\genfrac{}{}{0pt}{}{NH}{N}{>}C_6O_2{<}\genfrac{}{}{0pt}{}{N}{NH}{>}C_6H_4$, is obtained by heating the previous compound with alcoholic hydrogen sulphide at 100° in a sealed tube; colourless crystals are formed in the tube, which immediately become bluish-black on exposure to air; the compound is deposited from a mixture of alcohol and benzene in dark-green, granular crystals, closely resembling those of homofluorindine; the glacial acetic acid solution is blue, and exhibits an intense characteristic fluorescence, especially on the addition of a little alcohol.

Quinoneorthonitrotoluidide, $C_6H_3O_2{\cdot}NH{\cdot}C_7H_6{\cdot}NO_2$ [O : NH : O = 1 : 2 : 4], the chief product of the action of quinone on nitroparatoluidine, [Me : NO_2 : NH_2 = 1 : 3 : 4], is deposited from absolute alcohol in aggregates of red crystals, decomposing at about 300°.

Quinonediorthonitrotoluidide, $C_6H_2O_2(NH{\cdot}C_7H_6{\cdot}NO_2)_2$, is formed together with the previous compound; it corresponds in constitution to the nitraniline derivative, is more sparingly soluble in alcohol than the previous compound, and crystallises in bronze-coloured plates which decompose at 140°.

Quinoneparamethylphenazine, $C_6H_2O_2{<}\overset{N}{\underset{N}{|}}{>}C_6H_3Me$ [O : N : N : O = 1 : 2 : 3 : 4; Me : N : N : = 4 : 5 : 6], is prepared by the action of alcoholic ammonium sulphide on nitrotoluidoquinone at 100°; it forms a bronze-coloured, crystalline powder soluble in alcohol with a violet colour; the glacial acetic acid solution is greenish-blue, and on adding dilute sulphuric acid, it acquires a faint red fluorescence.

Nitranilidotoluquinone, $C_6H_2MeO_2{\cdot}NH{\cdot}C_6H_4{\cdot}NO_2$ [O : NH : O : Me = 1 : 2 : 4 : 6], is obtained from toluquinone and orthonitraniline; it is deposited from alcohol in red crystals, which decompose at 200°. By the action of alcoholic ammonium sulphide on this compound, *quinonephenotolazine*, $C_6HMeO_2{<}\overset{N}{\underset{N}{|}}{>}C_6H_4$ [N : N : Me = 2 : 3 : 5], is produced, crystallising in small, red plates, soluble in glacial acetic acid with a green colour; the solution exhibits a red fluorescence on the addition of dilute sulphuric acid.

Nitrotoluidotoluquinone, $C_6H_2MeO_2{\cdot}NH{\cdot}C_6H_4Me{\cdot}NO_2$ [NH : Me = 2 : 6], obtained from toluquinone and nitroparatoluidine

[Me : NO_2 : NH_2 = 1 : 3 : 4],

crystallises in brown plates. On reduction, this compound yields *quinonetolazine*, $C_6HMeO_2{<}\overset{N}{\underset{N}{|}}{>}C_6H_3Me$ [N : N : Me = 2 : 3 : 5], which crystallises from alcohol in small plates with a dark-red sheen; it is soluble in glacial acetic acid, the colour of the solution being green; the addition of dilute sulphuric acid causes a faint red fluorescence.

Orthonitranilidonaphthaquinone is prepared from α-naphthaquinone and orthonitraniline; it is deposited from alcohol in straw-coloured crystals, which appear carmine-red in a finely-divided state; by the reduction of this compound, the corresponding *naphthaquinonephenazine*, $C_{10}H_4O_2{<}\overset{N}{\underset{N}{|}}{>}C_6H_4$, is obtained, crystallising from alcohol in green plates; the solution is brown, and has a faint green fluorescence. *Nitrotoluidonaphthaquinone* is formed from α-naphthaquinone and nitroparatoluidine, [Me : NO_2 : NH = 1 : 3 : 4]; it crystallises in lustrous, orange-red needles; the alcoholic solution is brownish-yellow. On reduction, *α-naphthaquinonetolazine*,

$$C_{10}H_4O_2{<}\overset{N}{\underset{N}{|}}{>}C_6H_3Me,$$

is obtained, crystallising from alcohol in steely bluish-green plates The alcoholic and glacial acetic acid solutions are greenish-yellow, and exhibit a faint green fluorescence. The compound dissolves in concentrated sulphuric acid with a green colour. J. B. T.

Attempts to Synthesise Conhydrine. By H. ALEXANDER (*Ber.*, **23**, 2714—2715).—From the resemblance between α-pipecolylmethylalkine, $C_5NH_{10}{\cdot}CH_2{\cdot}CHMe{\cdot}OH$, and the isomeric conhydrine, Ladenburg has expressed the belief that the latter compound is likewise an alkine In that case it would probably be an α-lupetidyl alkine, $C_5NH_{10}{\cdot}CH_2{\cdot}CH_2{\cdot}CH_2{\cdot}OH$, or an α-piperidylethylalkine,

$$C_5NH_{10}{\cdot}CHEt{\cdot}OH.$$

The author has endeavoured to prepare the lutidyl compound corresponding with the first-named alkine by acting on α-picoline with ethylene chlorhydrin. A base was thus obtained the *platinochloride* of which forms well-developed yellowish-red crystals melting at 200° with decomposition, and has the expected composition $(C_8H_{11}NO)_2,H_2PtCl_6$. The free base could, however, only be prepared in aqueous solution, all attempts to prepare the anhydrous compound resulting in the formation of resinous matter. The *aurochloride* of the base, $C_8H_{11}NO,HAuCl_4$, has also been obtained, and forms small, lustrous, yellow crystals which melt at 99—100°.

An attempt was also made to prepare lupetidylalkine by acting on α-pipecoline with ethylene chlorhydrin, but without success.

H. G. C.

Strychnine. By J. TAFEL (*Ber.*, **23**, 2731—2739).—Strychnine was suspended in methyl alcohol and boiled with methyl iodide in a reflux apparatus. It was thus converted into the methiodide, which was separated and decomposed with silver sulphate. The clear solution was then treated with barium hydroxide, the excess of the latter removed by sulphuric acid, and the solution filtered, and evaporated in a vacuum. *Methylstrychnine* then separated out in colourless or faintly yellow crystals with the composition $C_{22}H_{34}N_2O_7$; these, when dried in a vacuum and finally at 108°, lost water, yielding the colourless compound $C_{22}H_{26}N_2O_3$, which is very hygroscopic and readily takes up 2 mols. of water, forming the compound $C_{23}H_{26}N_2O_3 + 2H_2O$.

Methylstrychnine, when treated with methyl alcohol and methyl iodide, readily yields a methiodide, $C_{23}H_{29}N_2O_3I$, which is insoluble in ether, sparingly soluble in hot alcohol, and more so in boiling water. It decomposes above 280° without melting, and gives a blood-red coloration with strong nitric acid. By treatment with silver sulphate and barium hydroxide as above, it is converted into *dimethylstrychnine*, which crystallises from water in brilliant prisms with the composition $C_{23}H_{40}N_2O_9$. These lose water in a vacuum, yielding the compound $C_{23}H_{28}N_2O_3$. It dissolves easily in methyl and ethyl alcohol and hot water, very sparingly in ether; the aqueous solution is neutral, and is coloured blood-red by oxidising agents. The hydriodide dissolves in 15 parts of hot water, and crystallises from it in small plates. Its methiodide, prepared as above described, crystallises from water in colourless needles of the composition $C_{24}H_{31}N_2O_3I$, but when treated with silver sulphate and barium hydroxide, it yields, not a trimethyl-, but a dimethyl-strychnine derivative, $C_{23}H_{29}N_2O_3I$.

By heating strychnine (15 grams) with crystallised barium hydroxide (30 grams), and water (40 c.c.) for 12 hours at 140° in a tube, *strychnine dihydroxide* was formed, and precipitated by acidifying the solution with acetic acid; on dissolving the product in dilute aqueous soda and precipitating with carbonic anhydride, it is obtained in colourless needles of the composition $C_{21}H_{26}N_2O_4$.

By heating strychnine dihydrate with sodium methoxide and methyl iodide in a closed tube in the water-bath, the *methiodide* of *tetramethylstrychnine dihydroxide*, $C_{26}H_{37}N_2O_4I,2H_2O$, was obtained; it crystallises from water in long, thin needles which lose their water in a vacuum.

When working in the manner described by Loebisch and Schoop (Abstr., 1886, 814), for the preparation of "strychnol," a substance is obtained which is really *strychnine monhydroxide*, $C_{21}H_{24}N_2O_3,4H_2O$; this crystallises from water in colourless needles, and loses its water in a vacuum. C. F. B.

Crystalline Veratrine. By F. B. AHRENS (*Ber.*, **23**, 2700—2707). —In addition to the crystalline aurochloride described by Bossetti (*Arch. Pharm.*, 1883, 81), veratrine also forms a crystalline *mercurochloride*, $C_{32}H_{49}NO_9,HHgCl_3$, and *picrate*, $C_{32}H_{49}NO_9,C_6H_3N_3O_7$. The former crystallises in small, silvery plates which melt at 172° with decomposition, whilst the latter forms stable crystals which blacken at 225°, but may be heated still higher without undergoing further alteration. Both are very slightly soluble in water, but dissolve readily in alcohol.

Veratrine unites with bromine forming a *tetrabromide*, $C_{32}H_{49}NO_9Br_4$, which is an amorphous, yellow powder insoluble in water, but readily soluble in alcohol, ether, and chloroform. It readily loses 2 atoms of bromine, passing into the *dibromide*, $C_{32}H_{49}NO_9Br_2$, also a pale-yellow, amorphous powder.

The action of alcoholic potash on veratrine has been examined by Wright and Luff (Trans., 1878, 328), and that of alcoholic baryta solution by Bossetti (*loc. cit.*). The former investigators obtained tiglic acid and a new base "cevine" $C_{27}H_{43}NO_8$, whilst the latter found angelic acid and "cevidine," $C_{27}H_{45}NO_9$. The author has confirmed these results with the exception that in Wright and Luff's reaction he finds that angelic acid is first formed, and is converted by later reactions into tiglic acid. This decomposition takes place very readily, being brought about by cold aqueous potash, and also, though more slowly, by cold dilute ammonia. It also takes place when veratrine is heated with water at 200°, a large quantity of resin being simultaneously formed.

When the alkaloïd is boiled with concentrated hydrochloric acid, it yields tiglic acid, $C_5H_8O_2$, and a lustrous, ruby-red, crystalline mass, which is probably the hydrochloride of a new base. On treatment with nitric acid, veratrine is totally oxidised; with potassium permanganate, it yields acetic and oxalic acids, and with chromic acid, acetaldehyde and carbonic anhydride. On dry distillation, it yields tiglic acid and β-picoline, the properties of which correspond with that obtained from strychnine, and differ in several points from the synthetical 2-methylpyridine. When distilled with quicklime, veratrine yields β-picoline, β-pipecoline, isobutylene, and a combustible gas not absorbed by bromine. H. G. C.

Oxidation of Ecgonine. By C. Liebermann (*Ber.*, **23**, 2518—2522).—It has been shown by Einhorn (this vol., p 1010) that when anhydroecgonine is heated with hydrochloric acid it yields tropidine; it seemed probable, therefore, that ecgonine and tropine would give the same oxidation products under the same conditions, an assumption which is shown to be correct by the author's experiments.

When ecgonine (100 grams) is oxidised with chromic acid and sulphuric acid in the manner described by Merling (*Annalen*, **216**, 329), a brown, syrupy acid is obtained; on boiling this product with alcohol, there remains a considerable quantity (about 18 grams) of tropinic acid, identical with the compound obtained by Merling by the oxidation of tropine, and the alcoholic filtrate, on evaporation, yields a brown, semi-crystalline mass, from which an acid of the composition $C_7H_{11}NO_3$ can be isolated without difficulty.

Tropinic acid, $C_8H_{13}NO_4$, melts at 253° with decomposition (Merling gives 220—240° as the melting point), and is very readily soluble in water, but very sparingly in alcohol, and insoluble in ether and benzene; it decomposes carbonates, and seems to be a monocarboxylic acid. The *barium* salt, $(C_8H_{12}NO_4)_2Ba$, and the *calcium* salt, $(C_8H_{12}NO_4)_2Ca$, are very hygroscopic: the *zinc* salt crystallises in colourless needles, and the *lead* salt is soluble in water. The *silver* salt is very readily soluble in water, and is unstable. Tropinic acid is immediately oxidised by potassium permanganate, even in the cold. The *hydrochloride*, $C_8H_{13}NO_4,HCl + H_2O$, is crystalline, and melts below 100° with decomposition; the *aurochloride*, $C_8H_{13}NO_4,HAuCl_4$, crystallises in golden prisms, and the *platinochloride* is very readily soluble. The formation of tropinic acid from ecgonine affords fresh evidence of the close relationship existing between ecgonine and tropine.

The acid, of the composition $C_7H_{11}NO_3$, referred to above, separates from water or alcohol in well-defined crystals, melts at 117—118°, and is readily soluble in alcohol; it decomposes carbonates and forms soluble salts, but it does not reduce potassium permanganate like tropinic acid. The *silver* salt, $C_7H_{10}NO_3Ag$, is very readily soluble in water. The *calcium* salt, $(C_7H_{10}NO_3)_2Ca$, and the *barium* salt, $(C_7H_{10}NO_3)_2Ba$, crystallise in needles. The *hydrochloride* is a crystalline, deliquescent compound. About 14 grams of this substance are obtained by the oxidation of 100 grams of ecgonine. F. S. K.

Compounds of Hæmoglobin and Oxygen. By C. BOHR (*Compt. rend.*, **111**, 195—197).—Hæmoglobin seems to form, with oxygen, four compounds, which have the same spectrum, and similar curves of dissociation, but differ in the proportion of oxygen which they contain, namely, 0·4, 0·8, 1·7, and 2·7 c.c. of dissociable oxygen per gram. The details of the investigation will be published subsequently. C. H. B.

Physiological Chemistry.

Influence of Cooking on the Digestion of Beef and Fish. By M. POPOFF (*Zeit. physiol. Chem.*, **14**, 524—532).—The foods investigated were the fresh and smoked flesh of the ox, and of the eel and sole. Quantities of these, both raw and boiled, were submitted to artificial gastric digestion; the soluble products were, after a fixed time, estimated, and the undigested residue was also weighed. The general results obtained are as follows:—

1. Raw flesh is more easily digested than that which has been boiled; this difference is more apparent with beef than fish.

2. The length of time that the boiling lasts has also an effect; indigestibility and prolonged boiling, especially in the case of beef, going together.

3. After the two varieties of flesh have been cooked equally, beef is more digestible than fish.

4. The smoking of fish favours its peptonisation; this is true for both raw and cooked smoked fish. In the case of beef, smoking has just the opposite effect.

5. Admixture of fat with fish does not hinder its digestion, as is the case with mammalian meat, but rather assists it.

The following table gives the relative digestibility, with artificial gastric juice, of the various meats used:—

	Raw.	Boiled.	Smoked.	Smoked and boiled.
Beef	100·0	83·4	71·0	60·6
Eel........	71·1	68·9	91·3	—
Sole.......	66·8	60·6	106·1	—

W. D. H.

Effect of "Saccharin" on the Digestion of Albuminoïds. By A. STUTZER (*Landw. Versuchs-Stat.*, **38**, 63—68).—Commercial saccharin is a mixture of benzoic sulphinide and about 40 per cent. of benzoic parasulphonamide. Experiments made by the author in 1884 indicated a very slight but immaterial diminution in the amount of albuminoids digested by gastric juice. The following experiments were made with earth-nut cake, the albuminoids of which are very quickly digested:—(*a*) experiments with saccharin without gastric juice or hydrochloric acid; (*b*) action of varying amounts of saccharin on 100 milligrams of nitrogen, in the form of digestible albumin, in presence of 0·05 per cent. of hydrogen chloride; (*c*) same as (*b*), but with gastric juice also; (*d*) same as (*c*), but 10 per cent. and 15 per cent. hydrogen chloride were employed.

The results of experiments (*a*) show that the solubility of albuminoids in water is considerably diminished by the presence of saccharin. The experiments with gastric juice and acid show distinctly the disturbing influence of saccharin, although the action is less marked in the experiments in which the stronger acid was used. With regard to the practical use of saccharin, the author does not draw any conclusions from the above experiments, inasmuch as the amount taken by different persons has to be considered, and individual characters play an important part in digestion. It would be of interest to determine whether both constituents of saccharin have the same action in retarding digestion, or, if not, which of them has the greater effect (compare Strohmer and Stift, *Oesterr.-Ungar. Zeitsch. f. Zuckerind. u. Landw.*, 1 Heft, 1889). N. H. J. M.

Artificial Digestion of Agricultural Feeding Stuffs. By R. Niebling (*Chem. Centr.*, 1890, ii, 116—117; from *Landw. Jahrb.*, **19**, 149—188).—From the results of a series of comparative experiments which the author has made between the actual digestion of a feeding stuff by the animal and the artificial digestion by means of Stutzer's method, he concludes that the latter gives too high results, the excess depending on the concentration of the acid in the pepsin. As a simpler method than that of Stutzer, the following is recommended: the substance is heated just to boiling with 0·2 per cent. of hydrochloric acid, it is then neutralised with a few c.c. of aqueous soda, and finally treated with pancreas extract. The latter redissolves the albumin, which is precipitated when the solution is neutralised.

J. W. L.

Formation of Carbamide in the Dog-fish. By W. v. Schroeder (*Zeit. physiol. Chem.*, **14**, 576—598).—Stadeler and Frerichs made the statement originally that the organs of the selachian fishes contain a great amount of carbamide (*J. pr. Chem.*, **73**, 48). In the present research, two varieties of *Scyllium* were investigated (*S. canicula*, and *S. catullus*), but the latter, being the larger fish, gave more satisfactory results.

The urea was estimated in the blood, muscle, and liver, with the following results:—

The blood is richer in carbamide than either the muscles or the liver; the percentage is higher even than in normal human urine. The blood, moreover, coagulates very slowly. In mammals, muscular tissue contains little or no carbamide. Five experiments were then performed, in which the liver was extirpated; the carbamide was, at periods varying from 23 to 70 hours after this operation, estimated in the muscles; the mean percentage found was then 1·86, or practically the same as in the previous experiments. The results of the experiments on normal tissues are given in the following table:—

Tissue.	No. of estimations.	Percentages of carbamide.		
		Minimum.	Maximum.	Mean.
Blood	4	2·36	2·71	2·61
Muscle	5	1·82	2·16	1 95
Liver	7	1·01	1·89	1·36

How to explain the occurrence of so great an amount of carbamide in the body of these animals is a difficult matter: the most probable reason, however, appears to be sluggishness of the kidneys in excreting the carbamide which is formed. W. D. H.

Colouring Matter of Purpura lapillus. By A. Letellier (*Compt. rend.*, **111**, 307—309).—The appearance of the colouring matter (Abstr., 1889, 1207) is accompanied by the development of a penetrating odour closely resembling that of allyl sulphide. *Murex brandaris* and *M. trunculus* develop a very similar odour. The smell is also perceived when the crystallised photogenic compounds (*loc. cit.*) are exposed to light, and it is, therefore, not due to putrefaction of the fascia. No allyl sulphide could be definitely isolated from 6,000 fasciæ, but ether extracted a substance which contained sulphur, evolved ammonia when heated with alcoholic potash, and gave the cyanide reaction with ammonium sulphide and a ferric salt. Allyl sulphide is usually accompanied by the thiocyanate in the juices of plants, and probably this is also the case in the fasciæ of *Purpura lapillus*. Some evidence was also obtained of the presence of carbamides or thiocarbamides in the water which had contained the fasciæ, but this fact was not definitely established. C. H. B.

Animal Melanins and Hæmosiderin. By J. J. Abel (*Chem. Centr.*, 1890, i, 1007—1008; from *Arch. path. Anat.*, **120**, 204—217). Besides egg-albumin and bilirubin, which are formed from the hæmoglobin as the blood issues from the surrounding cartilage, dark-brown or black and colourless substances are formed, in which iron may be detected by means of ammonium sulphide and potassium ferrocyanide. The author concludes from this that the blue coloration observed on mixing blood with hydrochloric acid and potassium ferrocyanide is due to the presence of iron albuminate.

The composition of the black substances, the so-called pigments, is still unknown. The alkaline solutions of the animal carbohydrates give, with solutions of ferric salts, precipitates, from which the iron cannot be again separated, and the author, therefore, concludes that, because iron may be found present with the black pigments, it does not follow that it is contained in them. J. W. L.

Physiological Action of Thallium Salts. By J. Blake (*Compt. rend.*, **111**, 57—59).—Thallous salts injected into the veins act only on one nervous centre, namely, that controlling the pulmonary ganglions, whilst the thallic salts, under the same conditions, affect all the nervous centres. The author considers that this difference in behaviour, and the poisonous action of metallic salts generally, is connected with the vibratory movements of the metals as shown by the spectroscope. In thallous salts the metal is univalent, and its atoms have only one set of harmonic vibrations, whereas in thallic salts the metal is trivalent, and its atoms or molecules are the *locus* of several sets of harmonic vibrations. C. H. B.

Chemistry of Vegetable Physiology and Agriculture.

Reducing Power of Micro-organisms. By L. DE BLASI and G. R. TRAVALI (*Gazzetta*, **20**, 18—24).—The authors, in reply to some strictures of Leone's (*Gazzetta*, **19**, 504) on a former paper of theirs (*Gazzetta*, **19**, 440), maintain that ammonia is the only ultimate product of the decomposition of albumin by the micro-organisms which they examined. They consider the action of the germs to be throughout reducing, nitrification being a purely chemical phenomenon.

To ascertain whether any oxidising germs exist in the atmosphere, the authors have repeated Leone's experiments (Abstr., 1887, 615): two flasks each containing a litre of spring water and 6 drops of nutritive gelatin, and two similar flasks containing only 1 drop of gelatin, were exposed to the air for 80 days. Nitrous acid was detected in the liquids on the second day, and increased in quantity up to the 18th day, when it commenced to diminish, and finally disappeared on the 22nd, or in one or two cases on the 31st day. Traces of nitric acid were present in the water when taken; the amount gradually increased and diminished concurrently with the nitrous acid, only the original traces eventually remaining. Ammonia was found on the second or third day, increasing in quantity with the diminution of the nitric and nitrous acids; the amount ceased to vary after the 60th day.

Determinations of the nitrogen in the gelatin taken, and in the ammonia finally obtained, gave almost exactly the same results, showing that the conversion of the nitrogen into ammonia is quantitative. S. B. A. A.

Reduction of Nitrates by Micro-organisms. By T. LEONE (*Gazzetta*, **20**, 98—104).—The author has previously shown (Abstr., 1887, 615) that the power of reducing nitrates is common to a great number of germs when placed in conditions favourable to their development; in a solution of nutritive gelatin, for instance, the nitrates are at first destroyed either directly or with the intermediate production of nitrites; when, however, the nutriment is exhausted, nitrification of the ammoniacal compounds in the solution commences.

The quantitative determinations now made by the author prove that the nitric acid in nitrates is reduced to nitrogen gas, and is not converted into ammonia as generally supposed; a definite amount of ammonia is always produced by the growth of the germs, but this is the same whether the menstruum contains nitrates or not, the only difference being that, in the former case, the total formation of ammonia is more speedily effected. The nitrogen in nitrates is not absorbed by the germs, but is quantitatively evolved from the solutions in the free state.

The author has also observed that putrefaction is accelerated by the addition of a small quantity of a nitrate, but when more is added than is sufficient for the decomposition of the organic matter present, the excess is not acted on. It would, therefore, seem that nitrates are utilised by micro-organisms as sources from which they can draw a supply of oxygen for the decomposition of their organic nutriment more conveniently than from the atmosphere.

S. B. A. A.

Action of the Bacillus of Malignant Œdema on Carbohydrates. By R. Kerry and S. Fränkel (*Monatsh.*, **11**, 268—271; compare this vol., p. 542).—The bacillus was cultivated in flasks containing grape sugar (150 grams), peptone (7·5 grams), Kemmerich's meat extract (15 grams), and feebly ignited calcium carbonate (75 grams) in 3 litres of water; the air in the flasks was displaced by carbonic anhydride.

The products obtained by adding oxalic acid and distilling were alcohol and butyric acid, whilst fermentation lactic acid and a little sarcolactic acid (from the meat extract) were left in the residue in the retort.

Nencki and Sieber (this vol., p. 78) obtained only butyl alcohol during the fermentation of sugar, while the authors obtain only ethyl alcohol, a difference to be accounted for by the individual nature of the bacillus employed.

A. G. B.

The Formation of Hydrogen Sulphide during the Alcoholic Fermentation. By L. Sostegni and A. Sannino (*Chem. Centr.*, 1890, ii, 112; from *Staz. sperim. agric. ital.*, 4, 434—447).—The authors fermented a sugar solution with a pure yeast culture. Flowers of sulphur were added, and hydrogen sulphide (which has frequently been observed during the fermentation of such solutions) was formed. The presence of air retarded the formation of hydrogen sulphide, but assisted the formation of alcohol. Since the yeast used was from a pure culture, the possibility of other ferments, causing the formation of sulphur, is excluded.

J. W. L.

Production of Ethereal Salts by Fermentation. By G. Jacquemin (*Compt. rend.*, **111**, 56—57).—Two equal quantities of sterilised barley wort were inoculated with a liquid which contained the lactic ferment, *Saccharomyces*, and the butyric vibrion, and one part was allowed to ferment with free access of air, whilst the other was kept out of contact with air, although the gases produced could escape. In the first case, the lactic fermentation took place; in the second, the liquid contained only traces of lactic acid, but yielded a somewhat high proportion of ethyl butyrate and of ethyl alcohol and its higher homologues. When the air is excluded the butyric vibrion, which is anaërobic, flourishes, but the lactic ferment, which is aërobic, loses its activity. The butyric acid produced by the vibrion, and the alcohol produced by the *Saccharomyces*, react at the moment of their formation, and yield ethyl butyrate.

In a similar manner, if pure *Saccharomyces ellipsoideus* is added to barley wort undergoing active lactic fermentation, ethyl lactate is formed. C. H. B.

Fat-decomposing Ferments in Plants. By W. SIGMUND (*Monatsh.*, 11, 272—276).—It was found that when oily seeds were macerated and shaken with water, the emulsion which was obtained contained more free fatty acid after some hours than it did at first, and from this it was concluded that some fat-decomposing ferment must have been present.

To isolate the ferment, the seeds (rape and castor-oil) were macerated with glycerol or water, and the extract precipitated with alcohol; the precipitate was washed with alcohol, dried at 30°, and finely powdered; a weighed quantity (0·2—0·5 gram) of it was then shaken with water and a weighed quantity (5—10 grams) of an oil (rape-, olive-, and castor-oils), and the emulsion allowed to stand for 24 hours, after which time the free fatty acids were titrated with decinormal soda and turmeric. The acidity of the oil was determined before the experiment, and a blank determination made at the same time as the other. In this way it was found that free acid was always produced by the alcohol precipitate; the results are tabulated in the paper, and, as an example, it may be quoted that 0·20 gram of alcohol precipitate from summer rape seed, acting on 5 grams of colza oil, produced acid equivalent to 51 milligrams of oleic acid.

As the alcohol precipitate might be pure albumin, and as albumin is known to more or less accelerate the decomposition of fats, experiments were performed, exactly as above, with pure egg albumin, but the amount of free acid found, after 24 hours, was very small. A. G. B.

Fermentation and Composition of Cranberry Juice. By E. MACH and K. PORTELE (*Landw. Versuchs-Stat.*, 38, 69—78).—Cranberry juice was allowed to ferment with yeast for nine days, either without further addition or with addition of grape must, and the alcohol determined. The results show that the juice will not ferment, and that this is caused by a substance present in the juice, and not in the skin, &c., of the berries. Similar results were obtained when a mixture of cranberry juice and must (equal vols.) was left to ferment; after 14 days, there was no sign of fermentation. With cranberry juice (1 part) and must (2 parts), fermentation began in 9 days, and in 14 days 3·88 per cent. of alcohol was formed. Löw

(*J. pr. Chem.* [2], 19, 312) showed that cranberries contain benzoic acid, and pointed out that this might be the reason that they do not decay for so long, and the author's experiments confirm this view. Neither oxalic, succinic, tartaric, nor salicylic acid is present.

The sp. gr. of cranberry juice from Bozen and from Hall varied between 1·0521 and 1·0661.

The following numbers show the amounts of different constituents in grams per litre of juice of cranberries, examined in 1888, from (A) Bozen, and (B) Hall:—

	Invert-sugar.	Total acid as malic acid.	Benzoic acid.	Tannic acid.	Nitrogen.	Ash.
A. Fresh berries—						
(*a*), 26th Sept. ..	92·00	19·11	—	2·24	0·12	2·98
(*b*), 6th Oct.	79·20	18·04	0·862	—	0·11	—
Soft berries—						
(*c*), 13th Nov. ...	118·00	19·92	—	—	—	—
B. (*d*), healthy, fresh, and hard, 14th Nov.	90·20	18·84	0·638	—	0·101	—
(*e*), soft and dried up, 14th Nov.	116·70	20·55	—	—	—	—

Juice from (*d*), examined later (21st March, 1889), contained: invert-sugar 73·80, total acid 22·33, volatile acid (as acetic acid) 3·25, alcohol 1·04, and ash 3·64 grams per litre. Juice from (*e*) contained, on 10th December, 1889, invert-sugar 41·10, acid 34·18, benzoic acid 0·759, volatile acid 15·20, and alcohol 3·42 grams per litre. The ash of (*a*) contained phosphoric acid 3·11, and potash 47·64 per cent.

Malic and citric acid may be present in considerable quantities.

Classen found that the bitter substance present in cranberries was identical with arbutin (*Jahresber. Agr. Chem.*, 1885, 362); in a subsequent examination of American cranberries, he could not detect arbutin, but found a substance (oxycoccin) which gave similar reactions to arbutin (*Bied. Centr.*, 16, 70).

The fruit and leaves of *Arctostaphylos uva ursi* do not contain benzoic acid. The arbutin which is present has no preservative action. Cranberry leaves contain no benzoic acid. N. H. J. M.

Chemical Composition of Vegetable Cell-membrane. By E. SCHULZE (*Ber.*, 23, 2579—2583).—The investigations of Steiger, Maxwell, Reiss, and the author have shown that many cell-walls contain not only a substance which is insoluble in dilute acids, and which, from its behaviour, is considered to be cellulose, but also certain carbohydrates which are quickly dissolved and decomposed by hot dilute acids, yielding galactose, mannose, and pentaglucoses.

The author has examined the insoluble cellulose of various vegetable products in order to determine whether it gives any other sugar than glucose on hydrolysis. The cellulose examined was obtained from skinned peas and lupine seeds, from coffee berries, wheat-bran, cocoa-nut, and the skins of lupine seeds; after removing the fat, albuminoïds, &c., the residual cellulose was treated with strong sulphuric acid, as described by Fleschig. The syrupy sugar prepared in this way, on oxidation with dilute nitric acid, gave saccharic acid in all cases, proving the presence of glucose; this result is in accordance with the view that cellulose is a polymerised anhydride of glucose. Further experiments proved that in some cases, at least, cellulose does not consist entirely of such an anhydride of glucose; the pure cellulose obtained from the seed-skins of lupines is coloured an intense violet-red when it is boiled with phloroglucinol and hydrochloric acid, and when the coloured substance is placed in a 50 per cent. solution of chloral, the latter also became coloured violet-red; cellulose from cotton-wool does not show this behaviour.

The cellulose from the seed-skins of lupines gives considerable quantities of furfuraldehyde on distillation with sulphuric acid, a fact which indicates the presence of a pentaglucose, but on hydrolysis with strong sulphuric acid, glucose is the only sugar that is produced.

The cellulose from coffee berries does not consist entirely of a polymerised anhydride of glucose, as, on hydrolysis with strong sulphuric acid, it yields a considerable quantity of mannose as well as glucose. Cocoa-nut cellulose seems to give the same two sugars under the same conditions, but the quantity of mannose produced is very small. F. S. K.

Cholesterin in Plants. By E. SCHULZE (*Zeit. physiol. Chem.*, **14**, 491—521).—The author, with J. Barbieri (Abstr., 1882, 1202), previously stated that lupine seeds and etiolated lupine seedlings contain cholesterin; the cholesterin was isolated, and weighed in a crystalline condition; further, it was shown that the percentage and total amount of cholesterin was greater in the seedlings than in the seeds, and the conclusion was therefore drawn that cholesterin is not one of the substances used up in the dark during the process of germination. Burchard (*Dissert.*, *Rostock*, 1889) has, however, challenged this assertion; for, experimenting with grass seeds, he found that the proportion of cholesterin in the seeds was greater than in the seedlings. He considers that in the experiments of Schulze and Barbieri the cholesterin was contaminated with impurities. The method by which he estimated cholesterin was the intensity of the colour reaction, described by Liebermann as the cholestol reaction; this is a green, fluorescent colour produced by the addition of acetic anhydride and concentrated sulphuric acid to a solution of cholesterin.

The present paper is largely polemical; it points out that Burchard experimented with grass and linseed, and not with lupines; that any evidence of the presence of impurities in the cholesterin obtained by Schulze and Barbieri is not only wanting, but that the evidence is all the other way; that the colorimetric method adopted by Burchard is rough and misleading, especially when used, as Burchard did use it, with impure extracts, that is, extracts containing fats and other substances which give tints with the reagents employed; that new experiments, details of which are given, confirm the older statements originally made; and lastly, that this is true not only for lupines, but also for the grasses and other plants used by Burchard.

W. D. H.

Poison of Corn Cockle Seeds (Agrostemma githago, Githago segetum). By Lehmann and Mori (*Ann. Agronom.*, 16, 381—382).—Corn cockle seed has been long recognised as poisonous. It contains, albuminoïds, 14·46; fat, 7·09; starch, 47·87; saponin, 6·56; cellulose, 8·23; ash, 3·97; water, 11·50 = 99·68. The saponin is the poisonous ingredient; apart from this, the seed is very nutritious. Fowls, pigeons, ducks, &c., die after eating these seeds; large doses are dangerous to cats, dogs, and pigs. Calves die after 18—20 hours when given 6—7 grams per kilo. of live weight; they recover after 4 grams per kilo. 3 to 5 grams of the flour produced symptoms of poisoning in the authors. The poisonous property is destroyed by baking or grilling the seed or flour in a stove; an aromatic odour is given off, and in the heated substance no saponin can be detected. One of the authors consumed 100 grams, the other 140 grams, of the cooked flour in 17 days, once as much as 35 grams in two days, without feeling the least ill effect. J. M. H. M.

Combustibility of Tobacco. By A. Mayer (*Landw. Versuchs-Stat.*, 38, 127—139).—In order to observe the effect of different substances, organic and inorganic, on the combustibility of paper, ordinary filter paper was soaked in 0·5 per cent. solutions. Paper soaked in tannin, peptone, resin, oxalic acid, sugar, glycerol, starch, dextrin, olive oil, calcium nitrate, and potassium hydrogen phosphate, burnt with flame, and offered resistance in putting out the flame. When paper was treated with potassium and sodium chloride, carbonate, and sulphate, potassium nitrate and citrate, sodium acetate and phosphate, and burnt, the flame was readily extinguished. On the other hand, the papers which burn well with a flame generally cease to glow within 10 seconds after the flame was put out, and those which burn badly (with a flame) will glow for over 100 seconds.

Organic substances of the most different kinds are favourable to combustion with flame and diminish the power of glowing, whilst inorganic substances generally have the opposite effect. The salts which are most favourable for glowing are: alkaline nitrates, sulphates, and carbonates, alkaline organic salts, and potassium chloride. Sodium salts have less effect than potassium salts, and calcium and magnesium salts much less still.

Dark ashes, containing carbon, were produced with paper treated with sodium nitrate, sulphate, phosphate, and borate, and with potassium phosphate and calcium chloride. Paper treated with potassium salts, magnesium sulphate, and sodium carbonate gave white ashes. With regard to the favourable effect sometimes produced by chlorides, it is suggested that this may be caused by a reduction of the salt, and the decomposition of water by the chlorine with liberation of oxygen. The fact that chlorides are favourable rather than unfavourable for the glowing of paper is of importance, and it may be assumed that this also holds good with tobacco. The more ash constituents tobacco contains, and the more potash present in the ash, and the less potash combined with fixed acids, the better the tobacco will burn. On the other hand, tobacco will burn badly when much phosphoric acid and lime are present; and the presence of much calcium chloride and sulphate is also unfavourable. The following table shows the percentage of some constituents in tobacco, of different qualities, from Sumatra:—

	Chlorine.	Potash.	Free alkali as K_2CO_3.	Ash	Nitrogen.
Good	1·5	5·9	4·9	20·5	2·7
Sufficiently good (light ash)	0·5	5·8	6·8	20·8	3·2
Sufficiently good	0·7	6·6	5·5	22·5	2·0
" " (grey ash)...............	1·2	7·9	4·1	17·7	3·3
Bad..................	3·3	4·6	0·5	18·5	2·6

The amount of free alkali is a better measure of combustibility than the amount of chlorine.

Tobacco which burns badly can be readily made to burn well by keeping for 24 hours in 0·5 per cent. potassium acetate or nitrate, and then drying. In this way soluble organic matter and the soluble chlorides are extracted, whilst the salts favourable to glowing are taken up. By using 0·5 per cent. solution of calcium acetate, the most incombustible tobacco, which can otherwise only be used for snuff, can be made to burn well and yield a quite white ash.

Exhaustion of Cultivated but Unmanured Soils: Drainage Waters. By P. P. Dehérain (*Compt. rend.*, **111**, 253—259).—Comparison of the volume of the drainage water with the volume of the rain, and analysis of the former, show that the sterility of unmanured soil (this vol., p. 406) cannot be attributed to any alteration in its power of retaining moisture, or in its capacity to furnish nitrates.

In order to avoid the great loss of nitrates in the drainage water which takes place in the late summer and autumn, the author suggests planting colza, rape, or some other rapidly growing crop, which, at the end of autumn or in the spring, is worked into the soil, and not only returns to it the nitrogen which would otherwise have been lost, but also furnishes a very beneficial organic manure.

C. H. B.

Composition of Straw. By A. Hébert (*Ann. Agronom.*, **16**, 358—371).—The author quotes the following analysis, made after methods long in use, to show the indeterminate state of our knowledge of the actual composition of straw:—Water, 14·05; ash, 6·98; nitrogenous substances, 3·12; crude fatty matters (ether extract), 0·99; sugars, 0·27; pectic substances, 0·70; crude cellulose, 31·40; starch and similar substances, 17·36; undetermined substances, 25·13—100·00. The weakness lies in the last two items. "Starch, &c.," is usually calculated from the quantity of reducing sugar produced by heating with an acid. The sugar produced in this way is a very indefinite quantity, varying with the treatment adopted; it may be, and is, produced from many substances other than starch; and, moreover, starch cannot be detected by the microscrope in the tissues of straw. Guided by Wheeler and Tollens' recent discovery of wood-gum, a substance which yields a special sugar, xylose, on hydrolysis with acids, the author has applied their process to straw, and has succeeded in extracting the same or a similar substance, namely, straw-gum, also yielding xylose on hydrolysis. The gum is obtained by extracting the straw for 48 hours with 5 per cent. soda in the cold, precipitating with alcohol, treating the precipitate with hydrochloric acid, repeatedly washing with alcohol, and drying.

The xylose produced from this gum by the action of dilute acids has the formula $C_5H_{10}O_5$, melts at 153—154° (the xylose of Wheeler and Tollens melts at 144—145°), is very soluble in water, soluble also in alcohol, reduces Fehling's solution, crystallises in prismatic needles, has a rotatory power of +18·63°, and a molecular weight of 146, determined by Raoult's cryoscopic method. On treating this sugar with phenylhydrazine hydrochloride and sodium acetate, crystalline needles are formed melting at 152—155°, very soluble in alcohol, less soluble in acetone, slightly soluble in water, characters identical with those of the xylosazone of Wheeler and Tollens formed in a similar manner. In accordance with this discovery of straw-gum, the author finds that, on distillation, with diluted sulphuric acid, straw yields furfuraldehyde identified by conversion into furfuramide. Wheat straw and oat straw both yield these products.

As regards the "undetermined substances," Muntz has concluded that amongst them must be a substance richer in carbon than the carbohydrates; this substance is, according to Deherain, the vasculose studied by Frémy. If from the total carbon, hydrogen, oxygen, and nitrogen found in straw are deducted the quantities of these elements contained in the known constituents, the residue has the percentage composition C 50·13, H 6·19, O 43·68. The constituent yielded by straw to the action of alkalis, and precipitable by hydrochloric acid, has for every 50·13 C, 4·86 of hydrogen, and 31·88 of oxygen = 86·87. Supposing the difference between 100 and 86·87, namely, 13·13, to consist of water (1·46 H + 11·67 O), and adding this to the previous figures, we get C 50·13, H 6·32, O 43·55 = 100·00, agreeing almost exactly with those of the undetermined straw residue, which, therefore, is concluded to consist of hydrated vasculose. The author has devised the following method of analysis to take account of the vasculose and straw-gum. After determining by old methods the moisture, ash, nitrogenous substances, and substances soluble in water and in ether, 2 grams of the straw exhausted by ether and by water are placed in a tube, 70 to 80 c.c. of 10 per cent. sodium hydrate solution is added, the tube sealed before the blowpipe, and heated in a paraffin- or oil-bath at 120° for three hours. During this treatment, the cellulose remains intact, the gum and vasculose dissolve. After cooling, the tube is opened, and its contents diluted to 150—200 c.c., filtered, the cellulose washed until free from alkali, dried at 110°, weighed, calcined, and the ash deducted. The filtrate is neutralised exactly by hydrochloric acid (turning from brown to light-yellow at the moment of neutralisation), evaporated to dryness on a water-bath. together with any precipitate which forms, and the residue treated with distilled water. The vasculose, which has been rendered insoluble by the drying, is left as a dense, granular residue, which is filtered, washed, dried at 110°, weighed. calcined, and the ash deducted. The straw-gum remains in the filtrate, to which, after concentration, 5 per cent. of hydrochloric acid is added, and the liquid heated in a closed vessel at 108° for two hours, or on a water-bath for five hours. The sugar in the filtered liquid is estimated by Fehling's solution, 10 c.c. of which = 45·4 milligrams of xylose = 43 milligrams of invert sugar. As the composition of the pure gum is unknown, it is reckoned as xylose in the analysis, and as xylose is a product of hydrolysis, the total obtained in this way is often a little over 100. The following analyses were made by this method:—

	Wheat straw.	Oat straw.
Water	10·40	8·05
Nitrogenous substances	2·42 (N = 0·388 p. c.)	3·57 (N = 0·571 p. c.)
Ether extract	1·18	2·98
Water extract, less ash (sugars, gum, tannin)	3·37	5·70
Cellulose	33·60	27·15
Vasculose	24·00	14·20
Straw-gum, reckoned as xylose	19·71	27·70
Ash	6·34	9·85
	101·02	99·20

Analytical Chemistry.

New Method of Colour Analysis by Means of the Tintometer. By J. W. Lovibond (*J. Soc. Chem. Ind.*, **9**, 10—15).—The instrument and method referred to in the paper is a new means of impartially judging the various colours, for recording the factors of colour which combine to form any given colour; and a system for registering the same, even in the most complicated combinations, and the most delicate shades, as well as in the deepest tints, which exist in nature. The instrument consists of two tubes, side by side, divided by a central partition terminating at the centre of the eyepiece in a knife edge, which, being inside the range of vision, is not noticed, so that light entering the openings at the opposite end, passes in equal quantities up each tube to the eye of the observer, giving a clear view of any opaque substances which may be placed outside or of transparent substances inside the tubes. The sides and central partition are grooved, in order to hide the edges of the measuring glasses, and of the gauged vessels for containing the liquids. Stops are placed at convenient distances to cut off light reflected from the sides, and the size and shape of the apertures introducing the light can be altered by means of diaphragms to suit small or irregularly shaped samples. The standard scale in connection with the apparatus consists of sets of coloured glass slips, all the glasses of each set being of the same colour, but each glass differing in depth of colour, the difference being in degrees of equal value throughout the scale. In all comparisons of a single colour, the starting point has been taken as a pure white. The standard used as a background for the glasses is pure calcium sulphate for small surfaces, and for large surfaces, as for the reflectors, the smooth side of Chance's opal glass. The new method is founded on the fact that neutral grey under certain conditions is always made by a combination of 1 red, 1·2 yellow, and ·2·4 blue in the original scales, and these proportions hold good at all depths. Then, by assuming these combining values of red, yellow, and blue to be units of their respective colours, a simple relationship of equality between these three primary colours is established, at least so far as the production of neutral grey is concerned. Having established this common equivalent as a unit of colour in reference to neutral grey, by removing the yellow equivalent a normal purple is left, by removing the blue a normal orange, and by removing the red a normal green, each being made up of equivalents of the two remaining primaries. If binary colour is taken to be the sum of any two colours composing it, then any departure from the normal towards either primary can be accurately measured and described. When a colour is composed of the three primaries, the units of neutral grey may be deducted as such, and the balance looked on as free colour. It also follows that by constant addition of neutral grey tints, a scale of equal degrees ranging from white to black may be established, and made available for measuring the penetrating power of light. The proportion of primary colours for the neutral grey standard the author has been dealing with is the result of observations taken in the open air, under a dull grey sky with light as nearly perpendicular as possible reflected from Chance's opal glass, and is the average of 324 observations made by nine persons. It was also found that all kinds of ordinary daylight between the first approach of twilight and direct rays from the sun are available for ordinary work, so that variations in the colour of daylight within wide limits do not alter the readings where the same light is used for both sides. D. B.

Oxidation of the Sulphur in Carbon Compounds. By BERTHELOT, ANDRÉ, and MATIGNON (*Compt. rend.*, 111, 6—9).—The substance is burnt, in presence of water (10 to 15 c.c.), in a calorimetric bomb containing oxygen under a pressure of 25 atmos. All the sulphur is converted into sulphuric acid, and it is only in the case of compounds containing very little hydrogen that any sulphurous acid is found in the bomb. In order to ensure complete combustion, substances of this character are mixed with a known weight of pure camphor.

The following determinations of sulphur were obtained by this method: egg albumin, 1·65, 1·59, and 1·59 per cent.; gluten, 0·90; wheat fibrin, 0·97; vitellin, 1·26; fibrin from calf's blood, 1·17; purified wool, 3·71 and 3·59. As examples of the applicability of the process to compounds rich in sulphur, the following results are given: thiophen, 38·06 and 38·07 (calc., 38·09); taurine, 25·4 and 25·3 (calc., 25·6); carbon bisulphide, 84·05 (calc., 84·2).

Wiborgh's Method for the Estimation of Sulphur in Iron and Steel. By J. B. Cohen (*J. Soc. Chem. Ind.*, 9, 16).—The apparatus consists of a wide-necked flask, holding from 250 to 300 c.c., to which is fitted a double-bored cork. Through one hole, a tap funnel is passed which terminates just below the cork, and through the other a cylindrical glass tube about 21 cm. long, open at both ends; the upper end of the latter is about 6 cm. in diameter, and the lower end is drawn out so as to pass through the hole in the cork. The amount of sulphur is determined by the depth of the yellow stain produced by hydrogen sulphide on the surface of a piece of calico previously soaked in a 5 per cent. solution of cadmium acetate and dried, the calico being stretched across the wide open end of the glass tube. The flask is first half-filled with water, and boiled on a sand-bath to expel air, the iron or steel (0·1 to 0·8 gram, according to the amount of sulphur) is quickly introduced, and the water again boiled for a few minutes, dilute sulphuric acid (1 in 5) is added gradually from the tap funnel, without interrupting the heating, until the iron is dissolved. Hydrogen sulphide is evolved, and this stains the calico. When the iron is completely dissolved, the boiling is continued for about 10 minutes, after which the calico is removed, well rinsed, and dried. The stain is then compared with a set of standards mounted on white cardboard, and kept for comparison. The weight of sulphur is determined by the following formula:—If w is the weight of the standard corresponding with the standard shade containing s of sulphur, and w_1 the weight of the sample taken, then the weight of sulphur s_1 in the sample is $s_1 = \frac{ws}{w_1}$.

D. B.

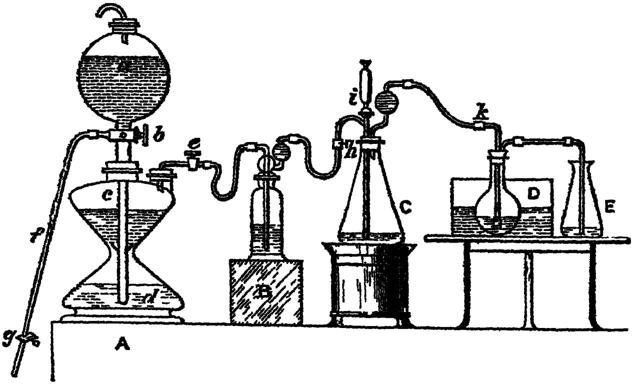
Determination of Sulphur in Iron and Steel. By L. Archbutt (*J. Soc. Chem. Ind.*, 9, 25—27).—5 grams of steel or iron is added to a previously heated mixture of 40 c.c. hydrochloric acid (1·10) and 20 c.c. nitric acid (1·42) contained in a large, lipped beaker; when the effervescence has ceased, a few crystals of potassium chlorate are added, and the solution is evaporated to complete dryness, and heated on the hot plate for at least half an hour, turning the beaker round occasionally so as to dry every part equally. When cold, the residue is heated with 20 c.c. more hydrochloric acid and again thoroughly dried; 40 c.c. of hydrochloric acid are then added and heated until a clear solution is obtained. The liquid is now cautiously evaporated until a skin begins to form, when the beaker is removed from the plate. 5 c.c. of hydrochloric acid is added, and boiling hot water is blown in from a wash-bottle until the solution is about double in volume. It is then at once poured on to a 10-cm. filter, which it just about fills, the beaker is rinsed two or three times with a very little more hot water, and the filter is covered up and allowed to drain. It is now washed, say twice, with cold water, and removed to another glass, where the rest of the silica remaining in the beaker is rinsed on to it and washed for the silicon estimation. The dark-coloured filtrate containing the sulphur as sulphuric acid, which should be less than 70 c.c. in bulk, is treated with 5 c.c. of a 10 per cent. solution of barium chloride, and left over night in the cold, or it is heated and filtered as soon as the precipitate has completely subsided. The solution is filtered, with or without suction, through a paper which has been previously washed with hydrochloric acid (which greatly hastens filtration) and the precipitate washed with cold water, dried, ignited, and weighed. From the weight is deducted that of the barium sulphate obtained in a blank experiment with the same quantities of hydrochloric and nitric acids. The precipitate is seldom, if ever, contaminated with iron, although the ash of the paper is generally pink. If there is any excess of iron present, it is easily estimated by heating the precipitate with hydrochloric acid, diluting, and making a colour titration with potassium thiocyanate. Some experiments were made for the purpose of comparing the results obtained by this method with those yielded by the evolution process, and it was found that whether the iron or steel is oxidised directly with aqua regia, or whether the sulphur is evolved as hydrogen sulphide, practically the same results are obtained; this supports the conclusion that a concentrated solution of ferric chloride, whether nearly neutral or strongly acid, has no appreciable solvent action on barium sulphate in the presence of barium chloride.

D. B.

Rapid Gravimetric Determination of Sulphur in Iron and Steel. By C. Reinhardt (*Chem. Centr.*, 1890, ii, 79—80).—The author recommends the use of the following method as being much more rapid for the determination of sulphur in iron and steel than those usually employed.

The apparatus consists of the following parts: a modified Kipp's hydrogen generator, A, a Drechsel's washing flask, B, an Erlenmeyer flask, C, an absorption flask, D, and a flask, E, used to test the gas as it issues for any traces of hydrogen sulphide which may have escaped absorption in D. The Kipp's generator has a three-way cock, *b*, to which is attached the tube *f*, by means of which the acid may be siphoned off when too far neutralised to be of further use. The Erlenmeyer flask has an acid-funnel, *i*.

The reagents required are: (1) soda containing a certain amount of sulphate, 500 grams of pure sodium hydroxide purified by alcohol, is dissolved in 2,000 c.c. of water, and after standing for several days, the clear solution is siphoned off into a well closed flask, carrying through its stopper a 100-c.c. pipette which reaches nearly to the bottom. Sulphuric acid (1 : 4) is added until 100 c.c. of the mixture contains sulphate equal to about 0·1000 gram of barium sulphate; (2) alkaline arsenious acid solution 10 grams is dissolved in 25 c.c. of ammonia (10 per cent.), and 175 c.c. of water by the aid of a gentle heat; (3) potassium permanganate, 6 grams in 1000 c.c. of water, used in B to purify the hydrogen. Before making a determination of the sulphur in iron, the exact amount of the sulphuric acid which 100 c.c. of the soda solution contains is determined in the same manner as the actual determination of the sulphur in the iron is carried out.



Of pig iron, 5 grams with 60 c.c. of hydrochloric acid, of cast iron or wrought iron, 10 grams with 100 c.c. of hydrochloric acid, is employed. The iron is placed in the flask C with 10 c.c. of water. The acid is put into the funnel above. 100 c.c. of the soda solution is put into the absorption flask D. Acid is now run in carefully from the funnel, and a slow current of hydrogen is passed through the apparatus from the generator A. After all the acid has been run into C, the liquid is brought to boiling. The hydrogen sulphide evolved from the iron is thus carried over into D, being there absorbed by the soda. At the conclusion of the reaction, this is transferred to a 500 c.c. flask, the sulphide oxidised with 20 c.c. of bromine-water, and after rendering acid with hydrochloric acid (sp. gr. = 1·19), it is heated to boiling, precipitated with 10 c.c. of barium chloride solution, the excess of bromine reduced with arsenious acid, allowed to remain for two hours, and the barium sulphate and the precipitate collected, washed, dried, and weighed.

The author recommends the employment of soda containing sulphate, because of the difficulty frequently experienced in filtering small quantities of barium sulphate perfectly. J. W. L.

Comparison of the Methods in Use for Estimating Organic Nitrogen. By R. W. ODDY and J. B. COHEN (*J. Soc. Chem. Ind.*, 9, 17).—The methods compared were those of Kjeldahl, Wanklyn, and Dumas. Colourless isinglass was selected as a typical albuminoïd substance. The analysis by Dumas' method gave the following percentages of nitrogen:—15·28, 15·20, 15·93, 15·22, and 15·74. As this method always gives too high a result, due to the difficulty of completely expelling all air from the tube, 15·2 per cent. may be taken as a close approximation to the truth. A portion of the same sample of isinglass was dissolved in water, and the amount of albuminoid ammonia determined exactly as described by Wanklyn in his book on water analysis. The authors found 12·75 per cent. of ammonia; Wanklyn gives 12·7 per cent. equivalent to 10·5 per cent. of nitrogen. As might have been anticipated, the percentage is much too low. Kjeldahl's process gave the following results: (1) With pure sulphuric acid, 13·50, 13·50, and 13·59 per cent. of nitrogen; (2) with a sample of commercial sulphuric acid, 14·12, 14·25, and 14·14; and (3) with another sample of commercial sulphuric acid, 15·8 and 15·2. Taking 13·5 per cent. as nearest to the truth, the result is very much too low in comparison with Dumas' process, which has stood the test of time. Although the majority of authors have obtained satisfactory results by Kjeldahl's process, and it is undoubtedly to be recommended in the case of the more readily decomposed organic compounds, as shown by the authors in the case of acetanilide, they are of opinion that in the case of the less easily decomposed compounds, the results have a tendency to be much too low. D. B.

Kjeldahl's Method for the Estimation of Nitric and Total Nitrogen. By O. FÖRSTER (*Landw. Versuchs-Stat.*, 38, 165—194; compare Abstr., 1889, 547 and 746).—*Estimation of Nitric Nitrogen.*—A weighed amount of a solution of potassium nitrate of known strength was evaporated to dryness in the flask used for the decomposition; in some cases the salt was weighed. When phenolsulphonic acid is used alone, the results are low, especially when an excess of phenol is employed. Very good results were obtained with phenolsulphonic acid and zinc-dust, but it was found that the addition of platinic chloride is not only unnecessary, but may readily give rise to a loss of nitrogen. The employment of zinc-dust requires great care owing to the violence of the reaction, and it is necessary to cool the flask (Märcker and Kühn, *Landw. Versuchs-Stat.*, 35, 445). It was found preferable to use sodium thiosulphate. The potassium nitrate is treated with sulphuric acid containing 6 per cent. of phenol and shaken until the nitre is dissolved. The amount of acid used is 30 c.c. for 1 gram of the salt. When the solution is complete, pure crystallised sodium thiosulphate (3—5 grams) is added, and after the reaction is over, mercury (0·5 gram) and sulphuric acid (20 c.c. for 1 gram of substance) are added. The addition of phosphoric anhydride and of potassium permanganate is unnecessary. The decomposition is effected in an egg-shaped flask of 150—200 c.c. capacity, with a neck about 18 cm. long. The author considers the open receiver usually employed for absorbing the ammonia to be unsafe, and recommends a wide U-tube of 500—600 c.c. capacity with bulbs. The reagents employed were examined for nitric acid, but were found not to contain sufficient to affect the results. It is not advisable to purify the sulphuric acid as recommended by Meldola and Moritz (*J. Soc. Chem. Ind.*, 7, 63), as the excess of nitrous acid cannot be entirely got rid of, and may give rise to a loss of nitrogen.

Experiments in which sulphosalicylic acid and sodium thiosulphate were used show that sulphosalicylic acid is preferable to phenolsulphonic acid (Scovell, Abstr., 1889, 308), one advantage being that the results are not affected by the presence of chlorine, which is of importance in the analysis of Chili saltpetre. The low results obtained when phenolsulphonic acid is used in presence of chlorides is attributed to the formation, and volatilisation, of chloropicrin; but this difficulty may be overcome by adding 10 c.c. of a 0 6 per cent. solution of silver sulphate to the nitrate solution before evaporating to dryness.

Estimation of Total Nitrogen —Known amounts of potassium nitrate were added to various organic substances, such as starch, paper, oxalic acid, &c., and the nitrogen determined, using phenolsulphonic acid and sodium thiosulphate. The results were all very satisfactory with the exception of those obtained when olive oil was used, which were too low.

A very good indicator for use in nitrogen estimations can be made by extracting commercial litmus (80 parts) with 20 per cent. alcohol (1000 parts), and adding malachite-green. Most indicators are influenced by carbonic anhydride and by ammonium salts. Phenolphthaleïn cannot be used. N. H. J. M.

Quantitative Estimation of Nitric Acid by Electrolysis. By G. Vortmann (*Ber.*, 23, 2798—2801).—A solution of the nitrate is placed in a platinum dish, together with crystallised cupric sulphate and dilute sulphuric acid, a feeble current of electricity is passed through the liquid until all the copper is deposited, and the solution is concentrated and distilled with excess of sodium hydroxide, the ammonia which is evolved being collected and determined in the usual manner. In the case of potassium nitrate, at least half its weight of crystallised copper sulphate should be employed; if less be taken, the current must be proportionately reduced. A salt of platinum or of mercury may be substituted for the cupric salt, or the positive electrode may be covered with copper. If relatively large quantities of nitrate are present, the direction of the current should be changed when all the copper has been deposited on the negative electrode; in these circumstances, a known quantity of sulphuric acid is added, and the excess remaining after the completion of the operation is titrated with one-fifth normal ammonia. The experiments were made in all cases with potassium nitrate, and the results obtained agree closely with the theory. J. B. T.

Estimation of Carbon in Organic Substances by a Wet Method. By J. Messinger (*Ber.*, 23, 2756—2760; compare Abstr., 1889, 80).—The substance is weighed in a small tube and placed in a flask of some 200 c.c. capacity containing 6—8 grams of chromic acid, so as not to touch the latter. The flask is fitted with a tap funnel, and is connected with a condenser inclined upwards. This is connected with a small combustion tube some 15 cm. long, drawn out at both ends, and containing copper oxide and lead chromate. This is joined to a drying apparatus containing both sulphuric acid and phosphoric anhydride, which is connected consecutively with a weighed potash-bulb apparatus, the ground tube of which is filled with soda-lime, with a weighed U-tube which contains the same substances, and lastly with an unweighed calcium chloride tube. A slow stream of air freed from carbonic anhydride is drawn through the apparatus, 50 c.c. of concentrated sulphuric acid is run on to the chromic anhydride, and the flask gently warmed until the anhydride dissolves. The decomposition of the substance then commences, and the flame is removed, but is replaced after 20 minutes, and the operation then continued for two hours. The gain in weight of the potash bulbs and soda-lime tube corresponds with the weight of carbonic anhydride derived from the combustion of the carbon in the substance examined. Good results were obtained with substances of varied chemical character. The small combustion tube must not be omitted, or the carbon will, in some cases, come out too low. C. F. B.

Method for Determining Alkalis in Presence of Sulphites. By J. GRANT and J. B. COHEN (*J. Soc. Chem. Ind.*, 9, 19—20).—A measured volume of hydrogen peroxide is run into a beaker, together with three or four drops of methyl-orange. As hydrogen peroxide is always slightly acid, a small quantity of a very dilute solution of sodium hydroxide (1 : 100) is added by means of a 1 c.c. pipette until the neutral point is reached. The requisite quantity of alkaline sulphite solution is next added, and boiled up at once, but gently. During the latter part of the boiling, the methyl-orange is bleached. The solution is cooled, a few more drops of methyl orange added, and the solution titrated with normal hydrochloric acid. From a series of experiments, the authors conclude (1) that the quantity of ordinary 10 per cent. hydrogen peroxide required depends on the percentage of sulphide present in the alkaline solution. The "caustic salts" of commerce contain about 50 per cent. of sulphite, hence it is sufficient to take 10 c.c. of commercial hydrogen peroxide for every 0·1 gram of the "salts" solution, although this gives twice the theoretical quantity of oxygen required to oxidise the sulphite to sulphate. For salts containing above 50 per cent. of sulphite, it is better to take double the volume of hydrogen peroxide. (2.) It is unnecessary to leave the mixture of alkaline sulphite solution and hydrogen peroxide for half an hour before boiling up, seeing that the increase in quantity of acid required for neutralisation is almost inappreciable. D. B.

Gas-Volumetric Analyses of Potassium Permanganate, Bleaching Powder, and Manganese Dioxide. By G. LUNGE (*J. Soc. Chem. Ind.*, 9, 21—24).—The author, in this paper, only treats of those of the numerous uses of the nitrometer in which hydrogen peroxide is employed as the principal reagent, and although the methods he refers to have been previously mentioned, the paper in question gives such data as amount to a conclusive proof of the correctness of the results to be obtained by this analytical method.

1. *Standardising Potassium Permanganate with Hydrogen Peroxide in the Nitrometer.*—In this case it is necessary to work with acid solutions containing a large excess of sulphuric acid. The permanganate employed was made from pure crystals, and was as nearly as possible semi-normal, namely, 1 c.c. = 0 004 gram of oxygen. It was standardised with iron wire; with crystallised oxalic acid, purified according to Winkler's process, and dried to constant weight in a Victor Meyer's air-bath at 56°; and with ordinary commercial hydrogen peroxide. The results were as follows:—

With iron wire	1 c.c. = 0·003999 gram oxygen.
With oxalic acid........	1 c.c. = 0·003997 „ „
With hydrogen peroxide.	1 c.c. = 0·004002 „ „

For 10 c.c. of permanganate, 30 c.c. of dilute sulphuric acid (1 : 5) and 10 c.c. of hydrogen peroxide should be used. The above numbers show that the standardising with hydrogen peroxide in the nitrometer is one of the most accurate methods, having the great advantage that it is carried out within an extremely short time without requiring a standard substance of accurately known composition.

2. *Estimation of Bleaching Powder or Bleach Liquor by means of Hydrogen Peroxide in the Nitrometer.*—The reaction which takes place is as follows:—$CaOCl_2 + H_2O_2 = CaCl_2 + H_2O + O_2$. It is not necessary to know the exact composition of the reagent, but, as it is desirable not to employ too large an excess, it is best to make a rough preliminary test by titrating the hydrogen peroxide with an excess of bleach solution. For analysis, the reagent should be diluted before use, so as not to give out more than 7 c c. of oxygen per c.c., and it must be made distinctly alkaline with sodium hydroxide up to the point at which a flocculent precipitate appears. The reading should be effected quickly, say, five minutes after mixing the liquids, otherwise the results will be too high owing to the gradual evolution of more oxygen from the alkaline liquid. In order to find the percentage of available chlorine by weight, it is necessary to remember that every c.c. of gas evolved, reduced to 0° and 760 mm., represents 0·003167 gram of chlorine. In practice it is best to dissolve 7·917 grams of bleach in 250 c.c. of water, and use 10 c.c. of the solution for each test, when every c.c. of oxygen evolved will directly indicate 1 per cent. of available chlorine. This involves the use of a 50 c.c. nitrometer. It is shown that the estimations are just as accurate when water is employed in the nitrometer as when using mercury. From the results of a large series of comparative tests, the author infers that the nitrometric method yields quite as concordant results in the testing of bleach as Penot's method, although by the former process there is about 0·2 per cent. more chlorine found, and

this amount might be deducted as a constant from the nitrometric results to bring them into entire concordance with those obtained by Penot's method.

3. *Analysis of Manganese Ore or Weldon Mud by means of the Nitrometer.*—In this case the reaction must take place in an acid solution. The finely-powdered ore is put into the outside space of the flask, and first treated with dilute sulphuric acid in order to decompose any carbonates present. The hydrogen peroxide is then introduced into the inner tube, the flask attached to the nitrometer, and the contents shaken up until the colour of the residue indicates the end of the decomposition. With Weldon mud the change is instantaneous. The reaction is illustrated by the equation $MnO_2 + H_2O_2 + SO_4H_2 = MnSO_4 + 2H_2O + O_2$. Every c.c. of gas evolved corresponds with 0·003897 gram MnO_2. Results are quoted showing that this method gives as accurate results as the ordinary iron sulphate process; and although for commercial purposes the latter will doubtlessly retain its supremacy, the nitrometric process offers the great advantage of a saving of time as well as dispensing with all standard solutions.

D. B.

Volumetric Estimation of Manganese. By G. VORTMANN (*Ber.*, **23**, 2801—2803).—The manganous salt, together with 2—3 parts of potassium alum, is dissolved in water and treated with excess of one-tenth normal iodine solution and pure sodium hydroxide; after warming for 5—10 minutes on the water-bath, the solution is cooled, diluted to a known volume, an aliquot part filtered, acidified, and the excess of iodine titrated with sodium thiosulphate solution.

Ferric sulphate may be employed in place of the aluminium salt; with the manganese alone, the results obtained are considerably too low. Potassium manganous sulphate was used for the determinations, and the results obtained agree closely with the theory.

J. B. T.

Estimation of Cobalt and Nickel. By J. HOPE (*J. Soc. Chem. Ind.*, **9**, 375—377).—The process consists of two operations:—(1) separation and determination of the cobalt by the "phosphate" method; (2) determination of the nickel by electrolysis. The phosphate method was originally devised by Dirvell (Abstr., 1880, 287), but it was not until modified by Clark (Abstr., 1884, 498) that its value as a means of separation was appreciated. The cobalt having been separated and weighed as pyrophosphate, the nickel is determined in the clear blue filtrate contained in a tall form of beaker, and measuring about 200 c c., in the following manner:—10 c.c. of strong aqueous ammonia is added, and the solution, after heating to about 70°, is immediately ready for electrolysis. For this purpose a battery of two 1½-pint size Bunsen cells is found to give the requisite strength of current, and is capable of depositing about 0·15 to 0·20 gram of nickel per hour. The electrodes consist of a sheet of platinum, shaped in the form of a cone, to the side of which a piece of thick platinum wire is rivetted, and a spiral formed of the same kind of wire, terminating in a straight piece. The spiral is then inserted in the solution, the cone is also suspended to cover, without touching, the spiral, taking care to have it wholly immersed in the solution. The battery is now connected, the cone with the zinc pole, and the spiral with the carbon pole, and the beaker covered with two halves of a watch-glass. The complete deposition of the nickel may be ascertained by drawing off a small quantity of the solution, which should not give the slightest coloration on addition of a drop of colourless ammonium sulphide. As soon as this is the case, the cone is removed, thoroughly washed in distilled water, then in alcohol, dried in a water-bath, and weighed. The weight of the cone having been previously noted, the increase found represents the weight of metallic nickel. D. B.

Analysis of Ferro-Aluminium and Aluminium Steel. By A. Ziegler (*Dingl. polyt. J.*, **275**, 526—528).—The analysis of ferro-aluminium may be effected by means of the process given by the author for ferro-chromium. Ferro-aluminium is composed of iron, aluminium, manganese, silicon, and carbon, and resembles ferro-tungsten in appearance. For analysis, 0 5 to 1 gram of the finely powdered and sifted sample is fused in a platinum crucible, half filled with freshly ignited hydrogen sodium sulphate. The melt is then extracted with hot water, and the residue containing silica filtered and washed with a 1 per cent. solution of hydrochloric acid. It is then tested with sulphuric and hydrofluoric acids as to the presence of any original substance not fully attacked. Any tangible residue left after this treatment is re-fused with the above flux, and the aqueous extract added to the above solution. The mixture is now deoxidised with sodium hypophosphite (10 c.c. of a solution containing 1 part of NaH_2PO_2 in 2 of water), the alumina precipitated by the addition of pure zinc oxide (suspended in water), and separated from the ferrous salt by filtration. The precipitate is dissolved in hydrochloric acid, and reprecipitated. It is then redissolved in hydrochloric acid, and the alumina precipitated with ammonia, redissolved in hydrochloric acid and reprecipitated. To ensure the absence of zinc and iron, it is recommended to fuse the precipitate (after ignition) with sodium carbonate, extract with water, reprecipitate the aluminium with carbonic anhydride, and filter. The filtrate is acidified with hydrochloric acid, and any alumina contained therein precipitated with ammonia. The precipitates are dissolved on their respective filters with hydrochloric acid. The alumina in the joint solutions is then precipitated with ammonia and ammonium chloride.

The analysis of aluminium steel may be effected in a similar manner, 5 to 10 grams of substance being used. As fusion with hydrogen sodium sulphate does not, however, invariably decompose the steel completely, especially when the substance to be analysed is in the form of borings, the author prefers to dissolve the steel in hydrochloric acid, separate the silica in the usual way, and submit the clear solution to the above treatment. Hydrochloric acid may also be employed for dissolving ferro-aluminium. D. B.

Rapid Estimation of the Principal Constituents of Cow's Milk. By Ballario and Revelli (*Bied. Centr.*, 1890, 540—541).—A comparison instituted between the results obtained by Soxhlet's aræometer and those obtained by the use of Marchand's lactobutyrometer, with the assistance of the tables corrected by the subtraction of 3·5 from every number, and the tables of Schmidt and Tollens, induces the authors to recommend the lactobutyrometer for all general purposes, so long as the percentage of fat lies between 1·3 and 4·5 per cent. The estimates of dry matter, as obtained by direct evaporation and by the use of Fleischmann and Morgen's formula as applied to the specific gravity, do not vary much the one from the other. For example, with a percentage of fat of 4·2, the range of differences found amounted to —0·07 to +0·33, when 46 samples were examined. Fleischmann's new formula (Abstr., 1885, 533) does not give such accurate results, the range of differences being +0·22 to —0·26.

E. W. P.

Estimation of Ash in Sugars. By E. Boyer (*Compt. rend.*, 111, 190—192).—5 grams of the sugar is mixed with 1 c.c. of water and heated gently, in order to convert it into caramel without carbonising it. It is then mixed with 2 c.c. of a solution of 25 grams of benzoic acid in 100 c.c. of alcohol of 90°, and is carefully heated until the alcohol is expelled. By gradually raising the temperature the sugar is carbonised, and the evolution of vapours of benzoic acid keeps the carbon in a very porous condition, so that it is readily burnt off in a muffle at a dull-red heat. This method removes the necessity for the uncertain corrections involved in the usual process.

C. H. B.

Detection of Impurities in Alcohol. By E. Mohler (*Compt. rend.*, 111, 187—190).—The reagents which gave the best results are sulphuric acid, magenta acid sulphite, aniline acetate, and potassium permanganate.

Sulphuric acid should be added in a volume equal to that of the alcohol; with a larger proportion pure alcohol gives a coloration, with a lower proportion the reaction is less sensitive. The following are the minimum proportions per litre which can be detected:—furfuraldehyde, 0·010 gram; capryl alcohol, 0·050 gram; isobutyl aldehyde, paraldehyde, acetaldehyde, and isobutyl alcohol, 0·125; propionaldehyde, œnanthylaldehyde, valeraldehyde, and amyl acetate, 0·250; formylcarbinol, acetylcarbinol, heptyl alcohol, and amyl alcohol, 0·500 gram. Alcohol containing 0·1 per cent. of butaldehyde, acetone, propyl, isopropyl, butyl, and methyl alcohols, and ethyl acetate, propionate, butyrate, isobutyrate, valerate, caproate, œnanthylate, sebate, benzoate, and salicylate give no coloration.

Magenta bisulphite varies in its action, according to the proportion of acid which it contains; the following solution gives good results:—Magenta solution (1 : 1000) 30 c.c., sodium hydrogen sulphite 34° B, 20 c.c., sulphuric acid 3 c.c., water 200 c.c. 10 c.c. of the alcohol under examination is mixed with 4 c.c. of this solution and allowed to remain for half an hour; it will detect in alcohol of 50° the following minimum quantities of impurities per litre: acetaldehyde and œnanthylaldehyde, 0·01 gram; valeraldehyde, 0·02; propionaldehyde and isobutaldehyde, 0·05: paraldehyde, furfuraldehyde, butaldehyde, and acetone, 0·50. Alcohols and ethers have no effect on the reagent; the colour developed is not proportional to the quantity of aldehyde present.

Aniline acetate is the special reagent for furfuraldehyde, and is not affected by other aldehydes, or by alcohols or ethers. Within somewhat wide limits the colour is independent of the proportions of aniline and acetic acid, but the best results are obtained by adding 10 drops of aniline and 2 c.c. of glacial acetic acid to 10 c.c. of the alcohol, allowing the mixture to remain for half an hour. The reaction will detect 1 part of furfuraldehyde in 1,000,000, and even in 10,000,000, and it may be applied in quantitative estimations.

Potassium permanganate in acid solution is immediately decolorised by paraldehyde, isobutaldehyde, and isobutyl alcohol. The reduction is very distinct, and is proportional to the quantity of these compounds present; it may, therefore, be applied in a quantitative manner. Acetaldehyde in the proportion of 1 in 1000 has no immediate reducing action on the permanganate. C. H. B.

Qualitative Test for Glycerol. By C. A. KOHN (*J. Soc. Chem. Ind.*, 9, 148).—Advantage is taken of two characteristic reactions:—(1) the formation of acraldehyde by the distillation of glycerol with hydrogen potassium sulphate; (2) the red coloration produced with a solution of rosaniline, decolorised by sulphurous anhydride, by acraldehyde, as by all aldehydes. The delicacy of the reaction has been tested, with the result that it is possible to detect 0·015 gram of glycerol. The reaction is not given by any of the following substances:—Manitol, cane-, grape-, or milk-sugar, starch, dextrin, albumin, gelatin, stearic acid, and oleic acid, but the carbohydrates interfere with the delicacy of the test, owing to the fact that their distillation products with hydrogen potassium sulphate hinder the formation of the red colour with rosaniline solution. D. B.

Volumetric Estimation of Phenols. By J. MESSINGER and G. VORTMANN (*Ber.*, 23, 2753—2756).—A known quantity of the phenol is dissolved in such a quantity of soda solution that at least 4 mols. of soda are present for every 1 mol. of the phenol; the soda should be free from nitrite. The solution is then warmed to about 60°, and decinormal iodine solution added until a strong yellow coloration is produced. The solution is then shaken, and warmed if required, when a precipitate forms. The solution is then cooled, acidified with dilute sulphuric acid, and diluted to 250 or 500 c c. An aliquot part, say 100 c.c., is filtered off, and the excess of iodine in it determined by titration with decinormal thiosulphate solution. The weight of iodine used in forming the precipitate, multiplied by a certain factor, gives the weight of phenol in the sample examined. The value of the factor is: for phenol, 0·123518; thymol, 0·2956772; β-naphthol, 0·37843106; and for salicylic acid, 0·18132606. In the case of these four phenols fairly accurate results were obtained.

C. F. B.

A Quantitative Reaction of Lignin. By R. Benedikt and M. Bamberger (*Monatsh.*, 11, 260—267).—When wood is submitted to the action of hydriodic acid, as in Zeisel's process for determining methoxyl (Abstr., 1886, 493), it yields methyl iodide. Since pure cellulose gives no methyl iodide, and various woods give just the same amount after thorough extraction with water, alcohol, and ether as before, the authors regard those portions of the wood known collectively as lignin, as furnishing the methyl iodide. Coniferin, coniferyl alcohol, and vanillin occur in quantities too small to yield any considerable amount of methyl iodide.

The methyl-number of wood thus becomes an approximate indication of its lignin contents. Taking Schulze's number, 54·1 per cent., as the amount of lignin in oak-wood, and calculating from the methyl-number, 28·6, given by oak-wood, the methyl-number of pure lignin becomes 52·9. On this basis the authors have calculated the amount of lignin in the woods tabulated below, the results being compared with those of Schulze:—

		Lignin contents.	
Sample.	Mean methyl-number.	Benedikt and Bamberger.	Schulze.
Nutshells	37·4	70·0	65·9
Oak	28·6	54·1	54·1
Alder	28·9	54·6	52·0
White beech	26·4	49·9	51·6
Acacia	24·2	45·9	47·0
Pine	21·3	40·3	42·0

The methyl-numbers of a variety of woods have been determined by treating 0·3—0·6 gram of the finely-divided wood, both air-dried and dried at 100° in Benedikt and Grüssner's apparatus (this vol., 299). The numbers vary between 20 and 31, and are approximately the same in different samples of the same wood. A table of the numbers is given in the original paper.

It is interesting to note that the methyl-number of lignite is 22·1; that of brown coal, 2·6; and that of true coal, 0.

The method may be useful in analysing paper. A. G. B.

Isocholesterin. By E. Schulze (*Zeit. physiol. Chem.*, 14, 522—523).—The cholestol reaction referred to in another paper is given, not only by cholesterin, phytosterin, and caulosterin, but also by the isocholesterin of sheep's wool, and the benzoyl compound of isocholesterin. W. D. H.

A New Method of Saponification. By A. Kossel and K. Obermüller (*Zeit. physiol. Chem.*, 14, 599—601).—Sodium ethoxide is recommended as the most convenient reagent for the saponification of ethereal salts of the fatty acid series. In place of using sodium ethoxide as such, sodium wire may be added to the ethereal alcoholic solution of the fat with equally favourable results. W. D. H.

Determination of the Fatty Acids in Soap. By M. SAUPE (*Chem. Centr.*, 1890, ii, 126; from *Pharm. Centralhalle*, 31, 314—315).—For the determination of the fatty acids in soap, the author recommends the following method, which is substantially the same as that employed by Liebermann and Wolff for the determination of fat in milk. 2 grams of the finely cut up soap is dissolved in a separating cylinder with 50 c.c. of water, 5 c.c. of hydrochloric acid is then added, and the free fatty acid is extracted with 54 c c. of ether saturated with water. After the ether has separated, 20 c.c. is measured off into a beaker, the ether evaporated, and the residual fatty acids weighed. J. W. L.

Detection of Salicylic Acid in Wine. By MEDICUS (*Chem. Centr.*, 1890, ii, 28—29; from *Pharm. Centralhalle*, 31, 321).—The author has observed the ferric chloride reaction in wines which have been undoubtedly free from salicylic acid. He has found that this is due to the presence of a yellowish oil, volatile with steam, sparingly soluble in water, readily so in ether, which was obtained from a large quantity of grape juice. He recommends that only 50 c.c. of wine shall be extracted for salicylic acid, instead of 100 c.c. (as recommended by Röse), and that the residue of the extract shall be treated with at least 10 c.c. of water, instead of 5 c c.

J. W. L.

Analysis of Diuretin. By G. VULPIUS (*Chem. Centr.*, 1890, ii, 27—28, from *Pharm. Centralhalle*, 31, 311—314).—Under the name diuretin, a diuretic has lately been introduced, consisting of a double salt of sodium theobromine and sodium salicylate. It is prepared by dissolving 180 parts (1 mol.) of theobromine in a solution of 40 parts (1 mol.) of sodium hydroxide, and adding 160 parts (1 mol.) of sodium salicylate, after which the double salt is obtained by concentrating the solution, 362 parts being obtained.

Diuretin, $C_7H_7N_4O_2Na,OH{\cdot}C_6H_4{\cdot}COONa$, is colourless, odourless, and readily soluble in water; its physiological action is unaccompanied by other adverse influences, and is quite distinct from *caffeineo-sodium salicylicum*. It should contain 4·97 per cent. of theobromine. The analysis consists in the estimation of the theobromine and salicylic acid.

The theobromine is determined thus:—2 grams of diuretin is dissolved in 10 c.c. of water in a porcelain dish, the solution neutralised with 5 c.c. of normal hydrochloric acid, and then rendered just alkaline with one drop of dilute ammonia. It is frequently stirred for three hours at the ordinary temperature, and the theobromine may then be transferred to a tared filter, the filtrate being used to wash into the filter what remains in the dish; gentle suction will remove the last portions of the filtrate, and the theobromine is finally washed with 2 portions of 10 c.c. of cold water, dried at 100°, and weighed. The author has found that the weight varies between 0 82 and 0·83 gram of theobromine in the case of pure diuretin, 0·13 gram remaining in the filtrate and washings, which together represent 48 per cent., and he considers that at least 46·5 per cent.

should be found. The theobromine should melt when carefully heated, should sublime, should leave no residue when burnt, and should dissolve readily in sodium hydroxide.

To determine the salicylic acid, the filtrate from the theobromine, together with the washings, is shaken in the separating funnel with 30 c.c. of ether, 2 grams of 25 per cent. hydrochloric acid is added, again shaken, separated, and the ether distilled off; the salicylic acid remaining should weigh 0·77 gram.

To prove the absence of a caffeïne preparation, 1 gram of the suspected diuretin is dissolved in 5 c.c. of water, and neutralised with hydrochloric acid, when theobromine should cause a milky precipitation, which should redissolve readily in aqueous soda, and if the mixture be shaken with its volume of chloroform, not more than 0·005 gram of residue should remain on evaporation of the latter.

J. W. L.

Quantitative Estimation of Colouring Matters by means of their Absorption Spectra. By T. L. Patterson (*J. Soc. Chem. Ind.*, **9**, 36—41).—In 1873 the author devised a method for estimating the amount of colouring matter in solutions which gave band spectra, by adapting a glass tube to the low power objective of a microscope, which worked vertically in a larger tube fitted to the sub-stage. On examining the light transmitted through a coloured solution placed in the lower tube by means of a spectrum eye-piece, having a comparison prism, over which was adjusted a sealed tube containing the standard solution, he was able to determine the height of a column of liquid of known strength which gave the same band absorption as the tube over the comparison prism. The height of the column of liquid was adjusted by means of the sub-stage pinion, the head of which was graduated for the purpose. On placing another solution of unknown percentage, but known strength, in the sub-stage tube, and adjusting the height of the column to give the same absorption as before, the two spectra being viewed alongside each other in the eye-piece, it was easy to calculate the value of the unknown one. The author used this apparatus occasionally, but the method is tedious and requires very careful adjustment of the light and all the parts of the instrument, in addition to which the separate comparison of two columns of liquid against a standard necessitates two readings, and consequently doubles the errors. In order to avoid these, he tried to adapt a slit and spectrum eye-piece to Laurent's colorimeter, and after some difficulty succeeded in fitting an adjustable slit just over the reflecting prisms, and by adapting the prismatic eye-piece of a microspectroscope, obtained an instrument which worked perfectly. The slit opens out wide, and, as now designed, the instrument may be used with the eye-piece suited for each, either for colorimetrical or spectroscopic work, qualitative or quantitative. In using the instrument, light reflected from the mirror beneath passes axially up through the solutions in the two tubes and movable columns, where it is received on the plane faces of two prisms, cut so as to totally reflect the light twice at right angles. Both beams now pass the slit in a divided "slice" of light, which is analysed by a direct-vision spectrum eye-piece, in which two spectra of equal intensity are seen. Gas or lamp light is better for this work than daylight, as it has no absorption lines to interfere with the bands; and the less refrangible end of the spectrum is brighter than with any but direct solar light. It is best to use a screen to shade extraneous light from the eyes. A little micrometer is adapted to the eye-piece by which the bands or lines can be measured or mapped. The Fraunhofer and bright line spectra can of course be examined as well with this instrument as with any other, but the dispersion being necessarily small, it is not possible to measure the lines with any degree of accuracy. This spectroscope is properly adjusted for work and ready for use, when the slit has a proper width, and the two spectra are seen in the eye-piece to have an equal intensity, and when the index of each cylindrical column points to zero on the scales, with the base of the column just touching the bottoms of the glass tubes. If now a solution of any colouring matter which absorbs light selectively, say, a dilute alkaline alcoholic solution of alizarine of known strength, be run gently into one tube from a pipette, the two characteristic bands which this body displays will be seen to come gradually into view on turning up the milled head of the glass cylinder and allowing the liquid to flow in between the base and the bottom of the glass tube. By raising or lowering the cylinder it is easy to get the exact thickness of liquid at which the bands are seen to the best advantage. If another solution of alizarine of unknown strength—it may be more or less concentrated—be run into the other tube, and the milled head turned so as to raise the glass column, a point is easily reached at which the two spectra viewed in the eye-piece are seen to be equal. On reading off the heights of the two columns, the strength of the unknown one is found to be inversely proportional to the height of the column and the strength of the known solution. Assuming the height of the standard column to be a, and its strength b, the height of the unknown column c, and its strength x, then x is found by the formula $\frac{ab}{c} = x$.

D. B.

Gantler's Method of Estimating Tannin. By H. R. Procter (*J. Soc. Chem. Ind*, 9, 260—261).—Referring to Gantler's process of estimating tannin, in which the determination is made with permanganate in a boiling solution (compare this vol., p. 430), the author finds that the amount of permanganate consumed is materially influenced by the excess of permanganate added and the amount of boiling to which it is submitted. The author considers it probable that by adherence to a rigid scheme of operation concordant results might be obtained, but such results could have at best but a comparative value, and no greater claims to accuracy than those obtained by the Löwenthal method.

D. B.

Analysis of Straw. By A. Hébert (*Ann. Agronom.*, 16, 358—371).—See this vol., p. 1459.

Examination of Acid and Compressed Fodders, and the Estimation of Total Nitrogen in them. By J. König (*Landw.*

Versuchs-Stat., 38, 227—234).—According to Kellner (*Landw. Versuchs-Stat.*, **32**, 56) there is a considerable loss of nitrogen in acid fodder if the ammoniacal nitrogen is not taken into account, and he suggests treatment with hydrochloric acid to prevent it. Woll (Abstr., 1889, 1030) found that the treatment with acid had no appreciable effect on the results. The following method is recommended:—The substance is cut up and mixed, and 100 or 200 grams or more, according to whether it is a material with fine or coarse stalks, weighed out, and gradually mixed with a mixture of 3 vols. of strong and 2 vols. of fuming sulphuric acid (100—150 c.c.) in a porcelain dish, which, with the pestle, was previously weighed. The solution of the substance may be aided by heating on a sand-bath. When a uniform paste is obtained, the whole is covered with a large watch-glass and left to cool in air free from ammonia. It is then weighed, and 30—60 grams (corresponding with 2—4 grams of dry matter) transferred to a flask of 500—600 c.c. capacity, for determination of nitrogen by Kjeldahl's method; 10—15 c.c. of sulphuric acid is added, and the whole heated over a small flame to drive off the water. The rest of the process is carried on in the usual manner. Very concordant results are obtained.

Farmyard manure may be analysed in a similar manner if it does not contain too coarse stalks. A small cube is first cut out with a sharp spade, well mixed in a dry barrel, a smaller sample taken from it, and 200—400 grams of this weighed and treated with acid.

Direct nitrogen determinations may also be made in liquids such as milk, urine, &c., by evaporating off the water in hard flasks after the acid has been added.

In estimating the free acids in acid and compressed fodder (sweet ensilage), 100 or 200 grams of the very finely-cut substance is kept for 5 to 6 hours in a 1 or 2 litre flask with 700 or 1500 c.c. of water. The flask is filled to the mark, the contents mixed, and filtered. 100 or 200 c.c. of the solution is titrated with $\frac{1}{4}$ or $\frac{1}{10}$ normal soda, with phenolphthalein as indicator; with strongly-coloured solutions litmus paper may be used. The volatile acid is determined by distilling 200 c.c. until 50 c.c remain, and titrating. The method is not exact, but the results are relatively correct.

To estimate fat, the substance extracted by ether should be shaken with water at 50—60°, filtered, and washed with warm water; it is then washed with absolute alcohol and finally with ether. The alcoholic ethereal solution is then evaporated down, and the residue dried at 100°, and weighed. N. H. J. M.

Analysis of Bootblacking. By F. M. Horn (*Chem. Centr.*, 1890, i, 950; from *Zeit. Nahrung. und Hygiene*, 4. 60).—The blacking is treated with boiling water, which dissolves out the portions soluble; the residue is then extracted with chloroform, which dissolves out the fat, and, finally, the residue is ignited, the mineral matter being thus determined, the difference being organic matters or carbon. In the aqueous extract any glucose may be determined according to Herzfeld's method, the glycerol by Benedikt and Cantor's method, and the free acid, if volatile, distilled and estimated by titration, any free sulphuric acid remaining in the retort. A sample had the following composition:—Calcium phosphate, 21·06 per cent.; gypsum, 3·02; sand, 3·07; carbon, 2·41; fats and fatty acids, 6·08; invert-sugar, 3·47; glycerol, 0·75; acetic acid, 2·10; free sulphuric acid, 1·01; water, 56·40; from which the author calculates the blacking to be made up from 80 grams of molasses mixed with 14 grams of sulphuric acid and 10 grams of acetic acid, and then added to 280 grams of fine bone-black and 60 grams of whale oil, water being finally added to the desired consistence. J. W. L.

—— hexachlor-α-diketohexene. 964.

Zincke, T., and C. **Campbell**, azimido-compounds, 787.

Zincke, T., and T. **Cooksey**, tetrachloro-α-diketohydronaphthalene and its decomposition products: orthotrichloracrylbenzoic acid and phthalylchloracetic acid, 781.

Zincke, T., and O. **Kegel**, action of bromine on phloroglucinol, 1108.

Zincke, T., and O. **Kegel**, action of chlorine on phloroglucinol, 488.

Zincke, T., and F. **Kuster**, action of chlorine on catechol and orthamidophenol, 751, 1255.

Zincke, T., and L. **Schmunk**, action of chlorine on quinonoximes, 1146.

Zinkeisen, W., oxalenediamidoxime and oxaleneanilidoximamidoxime, 122.

Zotta, V. v., zinc hydrosulphide, 214.

Zulkowski, K. and K. **Peters**, orcein, 1105.

Zuntz, N., and C. **Lehmann**, respiration in the horse during rest and work, 1170.

Zuschlag, G. See **Claus**.

Zuurdeeg, J. See **Klinger**.

INDEX OF SUBJECTS.

ABSTRACTS. 1890.

And also to Transactions, 1890 (marked TRANS.); and to such papers as appeared in the Proceedings during the Session 1889—1890 (Nos. 72 to 86; Nov., 1889 to July, 1890), but not in Transactions (marked PROC.).

A.

Abies excelsa, colouring matters of the cones of, 641.
Absorption of fat, 1171.
—— of ultra-violet rays by derivatives of the paraffins, 434.
Acenaphthenecarboxylamide, 158.
Acetaldehyde, action of hydrogen sulphide on, 478.
—— condensation of, with succinic acid, 584.
Acetamide, dichlor-, 190.
—— dichlorobrom-, 489.
—— thermochemistry of, 1360.
Acetamidodiphenyl sulphide, para-, 1292.
Acetamidophenylhydrazine, ortho-, 150.
Acetanilide, brom-, 268.
—— 1-2-3-dinitro-, 885.
—— 1-3-4-dinitro-, 887.
—— 1-3-6-dinitro-, 886.
—— testing, 1319.
—— thermochemistry of, 1360.
Acetanilidoacetic acid, 1415.
Acetanilidopropionic acid, α-, 1160.
Acetaniside, dinitro-, 751.
Acetic acid, chlor-, preparation of, 234.
—— —— electrochemistry and thermochemistry of, 99.
—— —— trichlor-, as a test for albumin, 312.
—— —— vapour density of, 1365.
—— —— vapour pressure of solutions in, 554.
—— anhydride, decomposition of, by water, 359.
—— chloride, preparation of, 234.
—— fermentation, action of light on, 1181.
Acetic-series, new acid of, 1395.
Acetic-series of acids, dispersive power of, 1353.
Acetoacetic acids, behaviour of ethereal salts of alkyl-substituted, with ammonia, 1097.
Acetobenzoylphosphinous acid, 619.
Acetocamphenylcarboxylic acid (?) 1152.
Acetoethenyl-β-naphthenylazoxime, 63.
Acetohydroxamic acid, 127.
Acetol, PROC., 1889, 156.
Acetometanitrobenzoic anhydride, 53.
Aceto-α-naphthol, 376.
Acetone, absence of, in healthy urine, 399.
—— action of ammonium formate on 784.
—— action of nitrogen iodide on, 1402.
—— action of sodium on, 956.
—— and benzoin, compound from, TRANS., 783.
—— estimation of, as iodoform, 837.
—— estimation of, in methyl alcohol, &c., 837.
—— tetrachloro-, derivatives of, 232.
—— tetrachlorobrom-, 189.
—— thio-, 26.
Acetonebenzile, preparation of, TRANS 673.
Acetoneberberine, 1011.
Acetone-chloroform, reactions and derivatives of, 959.
Acetonediacetic acid, 30.
Acetonedinitrophenylhydrazone, 40.
Acetone-ethylenephenylhydrazine, 251.
Acetonenitrophenylhydrazine, 151.
Acetonitrile, benzoyl-derivatives of, 1251.
Acetonuria and diabetic coma, 399.
Acetonylacetonemethylphenyldihydrazone, 24.
Acetonylacetoxime, 364.

Acetoparatoluidide, brom-, 269.
Acetoparatoluidoacetic acid, 415.
Acetophenone, oxidation of, by alkaline permanganate, 1116.
Acetophenoneacetonedioxime, 1155.
Acetophenonecarboxylanilide, chlor-, 785.
Acetophenone carboxylicacid, chlor-, 786.
Acetophenonenitrophenylhydrazine, 151.
Acetorthamidoquinoline, 1324.
Acetotoluidide, chlor-, 1285
Acetovaleric acid, Trans., 230.
Aceto-xylidide, parabrom-, 269.
Acetylacetone, chloro-derivatives of, 1394.
—— heptabrom-, 1110.
—— hexachlorodibrom-, 489.
—— octochlor-, 489.
—— perbrom-, 1108.
Acetylacetonemethylphenylhydrazine, 24.
Acetyl-ω-amidoethylpiperonylcarboxylic anhydride, Trans., 1016.
Acetylanhydroberberilic acid, Trans., 1041.
Acetylanisoil, para-, 963.
Acetyl-β-benzoylmetanitrophenylhydrazine, α-, 150.
Acetylbrazilein, dibrom-, 997.
Acetylbromothymol, 366.
Acetylcarbinol, Proc., 1889, 156.
Acetylcotarnelactone, 529.
Acetyl-αω-diethylcaproic acid, ω-, Trans., 36.
Acetyl-αω-diethylcaproic oxime, ω-, Trans., 37.
Acetyldithionaphthol, 1306.
Acetylditolyldiamidoethane, dichlor-, 1161.
Acetylene, condensation of, under the influence of the silent discharge, 961.
—— diiodide, isomeric varieties of, 594, 1219.
Acetylenedicarboxylates, action of phenylhydrazine on, 156.
Acetylenedicarboxylic acid, synthesis of aconitic acid from, 237.
Acetylenemercury, 119.
—— oxychloride, 119.
Acetylethylorthophenylenediamine, 612.
Acetylhydrastine, 649.
Acetylindole, [1′], 988.
Acetyllactic acid, 128.
Acetyllevulinic acid and its derivatives, 863.
Acetylmalic acid, 363.
Acetylmesoanthramine, 1426.
Acetylmetadiethoxybenzene, 964.
Acetyl-α-naphthenylamidoxime, 63.
Acetyl-β-naphthenylamidoxime, 62.
Acetyl-α-naphthyl ethyl ether, 964.
—— methyl ether, 964.
Acetyl-β-naphthyl ethyl ether, 964.
—— methyl ether, 964.
Acetylnaphthylamidoacetic acid, 901.
Acetylnitroethylalcohol, 858
Acetylorthamidoethylphenylhydrazine, 613.
Acetylorthamidophenyl phenylcarbamate, 761.
Acetylorthamidophenylmethylhydrazine, 613.
Acetylparadesylphenol, Trans., 968.
Acetylparamidobenzylphthalimidine, 487.
Acetylparamidothiophenol, 605.
Acetylparamidotriphenylcarbinol, 1141.
Acetylparamidotriphenylmethane, 1141.
Acetylphenanthraquinol, Proc., 1890, 31.
Acetylphenetoil, 963.
Acetylphenylamidoacetic acid, 623.
Acetylphenyl-α-amidocoumarin, 623.
Acetylphenyldichlorhydroxypyridone, 965.
Acetylphenylglycine, chlor-, 268.
Acetylpseudocumylhydrazine, Trans., 55.
Acetylpyrroline, α-, and benzile, condensation products of, 1000.
—— molecular weight of, 906.
Acetylquinol, thio-, 604.
Acetyltoluidide, nitropara-, isomeric modifications of, 1112.
Acetyltrichlorophenomalic acid, 365.
Acetyltrimethylenecarboxylic acid, Proc., 1890, 137.
Acetylurethane, action of phenylhydrazine on, 889.
Acetyl-values, Benedikt's, Proc., 1890, 72, 91.
Acetylxylenylamidoxime, 50.
Acid chlorides, formation of, by the action of sulphonic chloride, 1288.
Acids, aliphatic, determination of the structure of, 1098.
—— fatty, absorption of bromine by, 88.
—— —— acetyl values of, Proc., 1890, 72, 91.
—— —— action of phosphoric anhydride on, Trans., 532, 980.
—— —— dissociation of the salts of, in solution, 684.
—— —— in soap, estimation of, 1475.
—— influence of, on the evolution of gases by plants, 190.
—— of complex function, electrical conductivity as a means of investigating the interaction of, 204.
—— of the acetic series, dispersion of, 1353.

Acids of the sugar group, 1398.
—— —— —— —— reduction of, 597.
—— organic, affinity constants of, 1209.
—— —— saving effect on albumin of, in vegetable foods, 538.
—— unsaturated, 583.
—— —— action of methyl diazoacetate on the ethereal salts of, 736.
—— ——formation of racemic acid by the oxidation of, 1274.
Aconitic acid, synthesis of, from acetylenedicarboxylic acid, 237.
Acritol, *a*-, 468.
Acrosazone, *a*-, 468.
Acrylbenzoic acid, orthotrichlor-, 785.
Acrylic acids, substituted, 27.
—— —— —— action of aromatic amines on, 371.
Adenine, 534.
—— brom-, 535.
—— estimation of, 534.
Adipic acid, dibrom-, Trans., 371.
—— —— dichlor-, Trans., 939.
Adipomalic acid, 1239.
Ægirine from Brazil, 344.
Affinity coefficients, determination of, 4, 327, 1046.
—— —— of alkyl halogen compounds and of amines, 1366.
—— constants of organic acids, 1209
—— of organic bases, determination of, 5.
—— residual, of inorganic salts, 444.
Agrostemma githago, poison of the seeds of, 1458.
Air, absorption of ammonia from, by vegetable soils, 821, 822.
—— atmospheric, analysis of, 412.
—— composition of, 1370.
—— electrical conductivity of, due to the formation of ozone, 676.
—— estimation of moisture and carbonic anhydride in, 1188.
—— nitrous acid in, 406.
Air-bath, new form of, 546.
Alanine, *β*-, conversion of ethyl acrylate into, 862.
Alanine, heats of combustion and formation of, 936.
Albumin, composition of, 392.
—— decomposition of, by anaërobic ferments, 78.
—— decomposition of, by the bacillus of malignant œdema, 542.
—— digestible, of fodders, action of hydrochloric acid and pepsin on, 651.
—— egg, action of resorcinol on, 804.
—— —— crystalline, 182.
—— ——molecular weight of, 1216.
—— estimation of, in urine, 1199.
—— free from ash, preparation and properties of, 272.
Albumin, heat of combustion of, 938
—— saving effect on, of organic acids in vegetable foods, 538.
—— serum, gases evolved in the putrefaction of, 78.
—— trichloracetic acid as a test for, 312.
Albuminoïds, action of hot water on, 535.
—— effect of "saccharin" on the digestion of, 1450.
—— heat of combustion of, 938.
—— precipitation of, from urine, 273.
—— various, nutritive value of, 391.
Albumins, new reactions for, 1350.
Albumose from Jequirity seeds, toxic action of, 398.
Albumoses, reactions of, 804.
Alcaptonuria and uroleucic acid, 188.
Alcohol and benzene, products of the action of heated zinc-dust on a mixture of, 1429.
—— and piperidine, products of the action of heated zinc-dust on, 1429.
—— and pyrroline, products of the action of zinc-dust on, 1428.
—— and water, physical properties of 856.
—— commercial, detection of impurities in, 669.
—— detection of impurities in, 1472.
—— influence of, on the action of invertase on cane-sugar, Trans., 860
—— new method of titrating, with chromic acid, 1030.
—— pentatomic, 729.
—— purification of, 727.
—— supposed hydrates of, 857.
—— tetrahydric, from limonene, 1313.
Alcoholic liquids, examination and valuation of, 1194.
Alcohols, action of hydrobromic and sulphuric acids on, 465.
—— commercial, presence of furfuraldehyde in, 1400.
—— monohydric, dehydration of, 351.
—— of the fatty series, dispersive power of, 1034.
—— secondary closed chain, 506.
Aldehyde as the chief product of a fermentation, 1179.
—— in urine, 188.
—— test for, 1197.
Aldehydes, action of hydrogen sulphide on, 1092.
—— thio-, 25, 477, 478.
Aldol, 861.
Aldoximes, constitution of, 970.
—— isomerism of, 1121.
Alimentary canal, absorption of different fats by, 811.
—— —— decomposition of ethereal salts in, 1013.

Alkaline hydroxides, detection and estimation of, in presence of alkaline carbonates, 293.
Alkalis, estimation of, in presence of sulphites, 1468.
—— estimation of, in soils, 833.
—— estimation of, in water, 299.
—— influence of, on the action of invertase on cane-sugar, Trans., 852.
Alkaloïds, estimation of, in coca leaves, 310.
—— ferrocyanides of, 1318.
—— of the root of *Stylophoron diphyllum*, 649.
—— reactions of, 310.
—— utilisation and transformation of, during the germination of seeds, 543.
Alkanna red, detection of, in wine, 311.
Alkyl dicyanacetates, 1395.
—— haloïds and alkyloxides, affinity coefficients of, 4, 327.
—— hydrogen oxalates, 235.
Alkyldiazoamides, mixed, nature of the combination between, Trans., 798.
—— synthesis of, Trans., 785.
Alkylhydrastines and their derivatives, 1167.
Alkylisophthalic acids, symmetrical, 1283.
Alkylorthophenylenediamines and their derivatives, 611.
Alkyloxyquartenylic acids, ethereal salts of, 865.
Alkylpyrrolines, derivatives of, 65.
Allanite as a rock forming mineral, 460.
Allocinnamic acid, 1417.
Alloy, crystalline, of copper, tin, and lead, 335.
Alloys, application of hydrogen peroxide in the analysis of, 419.
—— behaviour of, near their freezing point, Trans., 387.
—— eutectic, of tin, Trans., 386.
—— of ferro-manganese and copper, electrical resistance of, 1356.
—— of gold and platinum, liquation of, 947.
—— ternary, 336.
Allyl imidophenylthiocarbamate, Trans., 302.
—— phenylimidophenylthiocarbamate, Trans., 303.
—— tribromide, action of ammonia on, 953.
—— trimethylammonium compounds, 356.
Allylamine salts, brom-, 229.
Allylbenzene derivatives, conversion of, into propenylbenzene derivatives and their dispersion and refraction, 748.
Allylbenzyl cyanide, 1142.
Allylcarbamides, intramolecular change of, into isomeric bases, 127.
Allyl-compounds, atomic re-arrangement in, 1081.
Allyldeoxybenzoïn, 1142.
Allyldiethylcarbinol, glycerol from, 121.
Allyldimethylcarbinol, glycerol from, 121.
Allylethylsuccinic acids, isomeric, 133.
Allylmethylpropylcarbinol, glycerol from, 121.
Allylorthotolylthiocarbamide, 160.
Allylphenylsemithiocarbazide, Trans., 262.
Allylphthalimide, 890.
Allylpropylene-ψ-thiocarbamide, 861.
Allylthiocarbamideallyl cyanide, 1104.
Allylthiocarbamidebenzyl cyanide, 1104.
Allylthiocarbamideethyl cyanide, 1104
Allylthiocarbamidepropyl cyanide, 1104.
Allylthiouramidocinnamic acid, ortho-, 1123.
Allyltriphenylpyrroline, crystallography of, Trans., 748.
Alnus glutinosa, calcium oxalate in the leaves of, 191.
Aloïn, acetyl-derivatives of, 639.
—— brom-, 639.
—— from Barbados, Curaçao, and Natal aloes, 639.
—— preparation of, 170.
Alum, sodium, 1059.
Alumina, action of magnesium on, 693.
—— and ferric hydroxide, relative basicity of, 1062.
—— crystallisation of, in hydrogen chloride, 1071.
—— estimation of, in phosphatic manures, 420.
—— estimation of, in soils, 833.
—— influence of, on the decomposition of potassium chlorate, Trans., 276.
—— precipitation of, by ammonia, 420.
Aluminite, new variety of, 454.
Aluminium, action of nitric acid on, 702.
—— action of sulphuric acid on, 701.
—— alkali silicates, 13.
—— amalgam, 110.
—— —— use of, in thermochemistry, 110.
—— and iron, interference of chromium with the separation of, 84.
—— antimonate, 216.
—— chloride, anhydrous, preparation of, 13.
—— —— preparation of, 108.
—— diffusion of, in plants, 818.
—— effect of, on the freezing point of tin, Trans., 385.

Aluminium, estimation of minute quantities of, in iron and steel, 548.
—— fluoride electrolysis of, in igneous fusion, 1040.
—— —— heat of neutralisation of, 680.
—— hydroxide, action of, on aluminium and ferric salts, 946.
—— —— action of, on iron salts, 946.
—— oxide and fluoride, fused, electrolysis of, 552.
—— potassium arsenate, 1378.
—— pyroarsenate, 1378.
—— sodium arsenate, 1378.
—— steel, analysis of, 1471.
—— sulphate, analysis of, 85.
—— —— normal, 1384.
Amalgams, 1204.
Amarantite, 454, 456.
Amber from Southern Mexico, 337.
Amethylcamphophenolsulphone and a nitro-colouring matter derived from it, 1153.
Amides, aromatic, reduction of, **Trans.**, 957.
—— formation of alkyl-derivatives of, 491, 973.
—— heat of formation of, 1359.
Amidic substances, effect of feeding on the secretion of, 278.
Amidines, formation of, 371.
Amido-acids, 621.
—— —— action of ethyl iodide on, 956.
Amidoazo-compounds, 614.
Amido-compounds, formation of thiocyanates from, 749.
Amido-group, displacement of, by halogens, cyanogen, and thiocyanogen, 971.
—— —— displacement of, by the cyanic acid residue, 971.
—— —— displacement of, by the sulphonic acid group, 1137.
Amidoximes, 253, 1265.
—— and azoximes, 41, 140, 141.
—— behaviour of, towards diazobenzene derivatives, 254.
—— cyanogen additive products of, 1120.
—— substituted, 43.
Amine hydrochlorides, dissociation of, in solution, 684.
—— salts, absence of rotatory power in, 228.
Amine-ethylenediaminechloropurpureocobalt salts, 954.
Amines, action of nascent nitrous acid on, 38.
—— aromatic, derivatives of, 1415.
—— —— tertiary, action of thionyl chloride on, 610.
Amines, aromatic, thio-derivatives of, 1306.
—— tertiary, compounds of, with acetic acid and its homologues, 1156.
Ammeline, properties and constitution of, 856.
—— synthesis of, 856, 1082.
Ammonia, absorption of, from the air by vegetable soils, 821, 822.
—— action of, on the halogen compounds of arsenic, 1052.
—— albuminoïd, dynamical theory of, 87.
—— catalytic formation of, from nitrates, 689.
—— combination of sodium and potassium with, 209, 560, 679.
—— combination of, with boron chloride and silicon sesquichloride, 690.
—— compounds of, with metallic permanganates, 947.
—— compounds of, with silicon bromide and chloride, 559.
—— emission spectrum of, 97.
—— estimation of, in sand and sewage, 1024
—— formation of, from free nitrogen, 1051.
—— in burnt magnesium, 1209.
—— in the nutrition of plants, 287.
—— nitrification of, 282.
—— Ruffle's method of estimating, 1024.
—— specific gravity of solutions of, 107.
Ammoniomercuric cyanides, 223.
Ammonionickel thiosulphate, 13.
Ammonium amalgam, existence of, 1204.
—— borofluoride, 561.
—— cadmium thiosulphates, 1057.
—— chloride, new form of, 694.
—— combination of alkali metals with, 450.
—— compounds, mixed quaternary, action of heat on the chlorides and hydroxides of, **Trans.**, 767.
—— —— quaternary, isomerism in, 475.
—— fluoroxyhypomolybdates, 703.
—— γ-hydroxycaproate, 880.
—— hypochlorite, **Proc.**, **1890**, 22.
—— magnesium phosphate, estimation of nitrogen in, 291.
—— molybdoiodate, 107.
—— potassium thiosulphate, 564.
—— pyroxyhexathiovanadate, 1381.
—— rhodium nitrite, 1382.
—— salts, apparatus for the estimation of nitrogen in, 1341.
—— —— interaction of hypochlorites and, **Proc.**, **1890**, 22.

Ammonium salts, function of, in the nutrition of higher plants, 79.
—— sulphate and sodium nitrate, comparative manurial value of, 287.
—— sulphide precipitate, qualitative analysis of the, 84.
—— thiovanadate, 1381.
—— triiodate, 107.
—— urate, thermochemistry of, 1041.
Amphibole of secondary origin, 1081.
Amyl alcohol in brandy from different parts of the German Empire, 1388.
—— iodide, purification of, 116.
Amylamine, chloro-, 952.
—— dichloro-, 952.
—— tertiary, 1388.
Amylbenzoyldextroecgonine hydrochloride, 913.
Amylcarbamide, 1388.
Amyleugenol, dispersion and molecular refractive energy of, 1202.
Amyl-α-naphthol, dispersion and molecular refraction of, 1201, 1202.
Amyl-β-naphthol, dispersion and molecular refraction of, 1201, 1202.
Amylohydrolyst, Trans., 531.
Amylthymol, dispersion and molecular refraction of, 1201, 1202.
Anæmia, pernicious, 400, 1017, 1177.
Analysis, colour, 1461.
Andesine from Bodenmais, 344.
Andropogon schœnanthus, oil of, 951.
Angelic acid, derivatives of, 862.
Anhydride-formation in acids of the succinic series, 479, 741.
Anhydrite from North America, 218.
Anhydroanisylphenylthiouramidoxime, 1265.
Anhydro-bases, preparation of, from amidomercaptans of the fatty series, 524.
Anhydroberberilamide, Trans., 1046.
Anhydroberberilanilide, Trans., 1047.
Anhydroberberilic acid, Trans., 991, 1037.
—— —— constitution of, Trans., 998.
—— —— salts of, Trans., 1037.
—— —— synthesis of, Trans , 1061.
—— chloride, Trans., 1012.
Anhydroglycolylphenylglycine, 245.
Anilides, preparation of, 759.
—— properties of, 758.
Anilidobenzoïc acid, metamidopara-, 374.
—— —— metanitropara-, 374.
Anilidobutyric acid, α-, 1159.
Anilidodinitrobenzyl methyl ketone, 773.
Anilido-3-diphenyl-5-phenylpyrrolidone, [1], Trans., 683.
Anilidoethylenephenylamidoacetic acid, 1160.
Anilidonaphthaquinone, orthonitro-, 1446.
Anilidopropionic acid, 1159.
Anilidopropionylanilidopropionic acid 1160.
Anilidopropylcarbamide, 977.
Anilidopropylphthalimide, 976.
Anilidopyrotartaric acid, pyridine- and pyrroline-derivatives from, 612.
—— —— β-, preparation of, 774.
Anilidoquinonedianil, 912.
Anilidotoluquinone, nitro-, 1446.
Anilidotoluquinoneanil, 912.
Anilidotrinitrotoluene, 486.
Aniline, action of nascent nitrous acid on, 38.
—— chlorination and bromination of, in presence of an excess of a mineral acid, 37.
—— citraconate, 368.
——.conversion of, into benzenesulphonic acid, 1137.
—— conversion of, into diphenyl, 972.
—— dibrom-, 165.
—— 1-2-3-dinitro-, 885.
—— 1-3-4-dinitro-, 886.
—— 1-3-6-dinitro-, 886.
—— isocinnamate, 1418.
—— salts, stability of, alone and in presence of water, 1361.
—— —— thermochemistry of, 1361.
—— sulphonation of, with potassium hydrogen sulphate, 1149.
Anilinetrisulphonic acid, non-existence of, 1287.
Anilpyrroylpyruvic acid, 1243.
—— anhydride, 1243.
Animal-cellulose, 227.
Animal-economy, origin of urea in, 184.
Animal-heat, 206.
Animals, action of related compounds on, 280, 813, 1018.
—— calorimetric investigation of heat production in, 182.
—— effect of oil of mustard in foods on, 539.
—— secretion of calcium carbonate by, 653.
Anisaldehyde and succinic acid, condensation of, 770.
—— reaction of albumin with, 1350.
Anisaldoxime, orth-, 1410.
Anisaldoximes, isomeric, 1122.
Anisamide, 491, 975.
—— reduction of, Trans., 957.
Anisamidine, 492.
Anisamine, orth-, 1411.
Anisenylamidoxime, 144.
Anisenylbenzenylazoxime, 145.
Anisenylcarbonylamidoxime, 145.
Anisenylethenylazoxime, 145.
Anisenylpropenylazoxime-ω-carboxylic acid, 145.
Anisidine, dinitro-, 752.

Anisidine, paranitroso-, 608.
Anisylidenepyridylalkine, 1438.
Anisimido-ethyl ether, 491.
Anisodus luridus, constituents of, 658.
Anisoil, chlorobenzenes obtained from, 365.
—— chloro-derivatives of, 240.
—— chloronitro-derivatives of, 240.
—— ε-dinitro-, 752.
—— paranitro-, reduction of, 1120.
—— synthesis of ketones from, 963.
Anisylacetamide, orth-, 1411.
Anisylamidoxime, 1265.
Anisylamidoximeethenyl, 1265.
Anisylazoximepropenyl-ω-carboxylic acid, 1265.
Anisylbromobutyrolactone, 771.
Anisylbutyrolactone, 771.
Anisylcarbamide, orth-, 1411.
Anisylhydroxybutyric acid, salts of, 771.
Anisylimidoximecarbonyl, 1265.
Anisylisocrotonic acid, 584, 770.
Anisylmethylnitrosamine, paranitro-, 608.
Anisylnitrile, 1265.
Anisylphenylcarbamide, orth-, 1411.
Anisylphenyluramidoxime, 1265.
Anisyluramidoxime, 1265.
Anorthite, 19.
—— formation of, 1080.
—— from Miyakejima, Japan, 718.
Anthochroite from Sweden, 114.
Anthracene and its homologues, 511.
—— decahydride, 637.
—— formula of, PROC., 1890, 102.
—— octohydride, 637.
—— perhydride, 637.
—— reduction of, 1146.
Anthracenedicarboxylic acid, [1 : 4], 512.
Anthracene-1 : 2 :-4-tricarboxylic acid, 512.
Anthracylpiperidine, tertiary, 1003.
Anthraquinone and its homologues, 511.
—— formation of, under certain conditions, 1425.
Anthraquinonedicarboxylic acid, 1 : 4-, 512.
Anthraquinone-1 : 2 : 4-tricarboxylic acid, 512.
Antimonates, 216.
Antimoniuretted hydrogen. See Hydrogen antimonide.
Antimony, detection and estimation of, 1193.
—— double fluorides of, 216.
—— effect of, on the freezing point of tin, TRANS., 387.
—— electrolytic estimation of, 294, 421.
—— estimation of, 830.
—— evidence of the occurrence of a new element in, 434.
Antimony oxide, influence of, on the decomposition of potassium chlorate, TRANS., 275, 277.
—— pentachloride, vapour-density of, 16.
—— sulphate, TRANS., 540.
—— sulphide, precipitated, composition of, 1217.
Antipyrin, test for, 309.
Antiseptic powers of isomeric organic substances, TRANS., 636.
Apatite-group, synthesis of minerals of, 709.
Apiole, 35, 518.
—— constitution of, 1294.
—— molecular weight of, 725.
Apione, constitution of, 1295.
—— diamido-, 1295.
—— dinitro-, 1295.
Apioneacrylic acid, 36.
Apionecrotonic acid, 36.
Apioneketonic acid, 1294.
Apionuleglyoxylic acid, 1294.
Apionol, 35.
—— constitution of, 1295.
Aplysiæ, blood of the, 810.
Aponic acid, 518.
Apophyllite from the French Creek mines, 113.
—— from the United States, 113.
Aqueous vapour, specific volume of, 207.
Arabinon, TRANS., 59.
Arabinose, heats of combustion and formation of, 1360.
Arabinosecarboxylic acid phenylhydrazide, 154.
Arabonic acid phenylhydrazine, 1398.
Argol, analysis of, 303.
Aricine, 803.
Aromatic acids, unsaturated, preparation of, 891.
—— alkyl ketones and their oxidation, 979.
—— compounds, mercury nitrate as a test for, 669.
—— —— new method of chlorinating, 882.
Aromatic-nucleus, constitution of, 238.
Aromite from Atacama, 455.
Arrack, analyses of, 1195.
Arsenic, action of ammonia and hydrogen phosphide on the halogen compounds of, 1052.
—— allotropic forms of, thermochemistry of, 679.
—— chloride, combination of iridium phosphochlorides with, 1069.
—— —— freezing point of, 331.
—— compounds of, 1053.
—— detection and estimation of, 1193.
—— estimation of, 923, 1026, 1193.

Arsenic, estimation of, by Marsh's method 1187.
—— estimation of, in iron, 194.
—— influence of, on steel, 567.
—— oxide, influence of, on the decomposition of potassium chlorate, TRANS., 277.
—— rapid method of estimation, 83.
—— reactions of, 1343.
—— trioxide, action of sodium hydrosulphide on, 1053.
—— use of the induction spark for detecting traces of, 922.
Arsenical pyrites, 454.
—— —— from Wunsiedel, 711.
Arseniuretted hydrogen. See Hydrogen arsenide.
Arsenovanadates, 1380.
Artar root, constituents of the bark of, 918.
Artarine, 918.
Artichoke, Jerusalem, germination of, 656.
Asarone, constitution of, 244.
Ascaris, respiration of various species of, 274.
Ash, estimation of, 196.
—— —— in food and drugs, 833.
—— —— in sugars, 1472.
—— of tobacco leaves, composition of, 1338.
Asparagine, heats of combustion and formation of, 936.
Aspartic acid, electrical conductivities and multiple affinities of, 204.
—— —— heats of combustion and formation of, 936.
Assimilation and transpiration, relation between the, produced by chlorophyll, 190.
—— of carbon by green plants from certain compounds, 818, 1021.
Astrophyllite, 1079.
Atacamite in Chili, 111.
Atelesite from Schneeberg, Saxony, 18.
Atmosphere in soils, 81.
Atmosphere. See also Air.
Atomic and molecular union, can Raoult's method distinguish between, 105.
—— coefficients, critical, 444.
—— refraction of the elements, 313.
—— volume of elements, influence of, on steel, relation between, 567.
—— weight of beryllium, 699, 1375.
—— —— of bismuth, 706.
—— —— of gold, 708.
—— —— of hydrogen, carbon as an impurity affecting the determination of, 1369.
—— —— of iridium, 1067.
—— —— of magnesium, 850.
Atomic weight of oxygen, 330, 1370.
—— —— of palladium, 17.
—— —— of zirconium, 705.
Atoms, arrangement of, in space in carbon compounds containing nitrogen, 348.
——. stereochemical and mechanical views with reference to single and multiple union of, and the changes of one into the other, 555.
Atropine and cocaïne, relation between, 1010.
—— ferrocyanide, 1318.
—— influence of, on the salivary secretion, 397.
Atropines, optically active, formation of, 74.
Aurichalcite, 218.
Aurora Borealis, spectrum of, 313.
Autoxidation, 208.
Azimides, 787.
Azimido-compounds, 787.
—— —— formula of, 990.
Azimidotolylphenylcarbamide, 780.
Azines, formation of, from orthodiamines and polyamines, 178.
Azobenzene bisulphide, 605.
—— dinitrodinitroso-, 1259.
—— dinitronitrosoparachlor-, 1118.
—— dinitroparachlor-, 1119.
—— dinitrosonitroparachlor-, 1118.
—— dinitrosoparachlor-, 1119.
—— ethylxanthate, 605.
—— metatrinitro-, 762.
—— nitronitrosoparachlor-, 1119.
—— orthoparatetranitro-, 1259.
—— orthotrinitro-, 762.
—— paratrinitro-, 1259.
—— tetranitroparachlor-, 1119.
—— trinitronitroso-, 1259.
—— trinitronitrosoparachlor-, 1119.
—— trinitroparachlor-, 1118.
Azobenzeneazoparachlorobenzene, trinitronitroso-, 1119.
Azobenzenenitroazoparachlorobenzene, trinitronitroso-, 1119.
Azobenzeneparachlorophenylhydrazine, trinitronitroso-, 1119.
Azobenzenephenylhydrazine, trinitronitroso-, 1119.
Azobenzylethylamidophenol, 1116.
Azo-colours from α-naphthylamine, dimethylaniline, and α-hydroxynaphthoic acid, 1148.
Azo-compounds, action of carbon bisulphide on, 248.
Azocumic chloride, 891.
Azohydrazine-compounds, 1115.
Azophenine, formation of, 614.
Azotoluene, nitro-derivatives of, 140.
Azotoluenes, 140.
—— trinitro-, isomerism of, 350.

Azoximes, 253.
—— and amidoximes, 41, 140, 141.
Azoxybenzene, metatrinitro-, 762.
—— orthotrinitro-, 761.
Azoxyethylbenzylaniline, 1116.
Azoxy-β-naphthylamine, α-, 631.
Azoxyphenol ethers, 1119.
Azoxytoluenes, 140.
Azoxytoluenes, para-, isomerism of, 350.

B.

Bacillus ethaceticus, 916.
—— *fluorescens liquefaciens*, chromogenic functions of, 655.
—— —— *putridus*, chromogenic functions of, 655.
—— *liquefaciens magnus*, 78.
—— —— —— decomposition of gelatin by, 543.
—— of malignant œdema, action of, on carbohydrates, 1454.
—— —— —— decomposition of albumin by, 542.
—— *Rauschbrand*, 78.
—— —— decomposition of gelatin by, 543.
—— *pyocyanicus*, chromogenic functions of, 655.
—— —— colouring matters and aromatic products from, 189.
—— *spinosus*, 78
—— *viscosus sacchari*, 77.
—— *vini*, 77.
Bacteria, cholera, reduction of nitrates by, 76.
—— *emphysema*, 78.
—— ferment action of, 916.
Balance, gas, 823.
Balsams, analysis of, 1032.
Barium and strontium, separation of, 826, 924.
—— antimonate, 216.
—— benzylanthraceneulphonate, 1145.
—— cadmium thiosulphates, 1058.
—— carbonate, commercial, impurities in, 826.
—— di-β-naphthylketoneoxidesulphonate, 510.
—— dinitro-β-naphthol, 1424.
—— estimation of, in foods, 195.
—— hydroxide, decomposition of, by heat, 850.
—— oxide, action of magnesium on, 452.
—— —— dimorphism of, 850.
—— oxides, influence of, on the decomposition of potassium chlorate, TRANS., 280.
—— plumbate, 561.
—— rhodium nitrite, 1382.
Barium silicofluoride solubility of, 925.
—— sulphate, analysis of, 1027.
—— —— deposits of, from mine water, 853.
—— —— —— from Perkins' Mill, Quebec, 572.
—— toluenesulphonamate, [ortho-], 1137.
—— xylenesulphonamate, 1137.
Barley, culture of excised embryos of, on nutrient solutions, TRANS., 483.
—— culture of excised embryos of, on water, TRANS., 482.
—— estimation of starch in, 928.
—— malted, distribution of diastase in, TRANS., 508.
—— structure of the grain of, TRANS., 461.
Barysite, a new lead silicate, 456.
Baryta-raffinose, 580.
Barytes, occurrence of, near Torda, 713.
Bases, organic and inorganic, relative affinities of, 1367, 1368.
—— —— determination of the affinity of, 5.
—— —— volatile, equilibrium and reciprocal displacements between, 1362
Batatas edulis, carbohydrates of the, 1022.
Bath, air-, new form of, 546.
Batteries, measurement of the internal resistance of, 315.
—— secondary, theory of, 315, 1354.
—— storage, chemistry of, 842.
—— with fused electrolytes, 551.
Battery, gas, new form of, 811.
—— secondary, theory of, 315, 1354.
Beech, boric acid in, 656.
—— cupules of the, amount of mineral matter in and manurial value of, 287.
Beef, influence of cooking on the digestion of, 1450.
Beer, estimation of glycerol in, 426.
Beeswax, detection of ceresin, ozokerite, and paraffin in, 421.
Beet, sugar, in the experimental plots at Grignon in 1889, 820.
Beetroot, manurial experiments with, 1022.
—— the rôle of sugar and its development during the growth of the, 1020.
Belladonine, 271.
Benzalacetone, metamido-, 1138.
Benzaldehyde and ammonia, action of, on diacetyl, TRANS., 8.
—— and ethyl cyanacetate, condensation product of, 1270.
—— and pyrotartaric acid, condensation of, 775.
—— occurrence of benzamide in the urine after the administration of, 188.

Benzaldehyde, reaction of, with albumin, 1350.
Benzaldehydes, isomeric dichloro-, and the naphthols derived therefrom, 619.
—— thio-, α-, β-, and γ-, 25.
Benzaldoxime, 141.
—— a dimolecular isomeride of, 1122.
Benzaldoximes, constitution of, 721.
—— isomeric, 1121.
Benzallevulinic acid, derivatives of, 375.
-dibromide, 496.
—— —— preparation of, 495.
—— acids, β- and δ-, 1129.
Benzamide in urine after administration of benzaldehyde, 188.
—— thermochemistry of, 1360.
Benzamidine, action of, on ethyl acetylmalonate, 496.
—— benzamidylacetylmalonate, 496.
—— metanitro-, 973.
Benzamido-orthobromothymol, para-, 602.
Benzanilide, thermochemistry of, 1360.
Benzeïn-group, dyes of the, 157.
Benzene, action of nitrous anhydride on, 1401.
—— action of selenic acid on, 50.
—— and alcohol, products of the action of heated zinc-dust on, 1429.
—— bromotriamidodinitro-, 982.
—— chlorination of, 882.
—— condensation of, under the influence of the silent discharge, 961.
constitution of, 238, 602, 881, 1004, 1105, 1275, 1283, 1432, and Proc., 1890, 101.
—— dichloro-, [para-], conversion of, into metadichlorobenzene, 882.
—— 1-2-3-dinitriodo-, 886.
—— 1-3-4-dinitriodo-, 887.
—— 1-2-3-dinitrobromo-, 885.
—— hexachloride, action of aniline on, 614.
—— hexachlorides, molecular weights of, 725.
—— hexachloro-, action of fuming nitric acid on, 882.
—— metamerism in derivatives of, 881.
—— monobromo-, the "second," 881, 962.
—— nitro-, action of chromium oxychloride on, Trans., 253.
—— —— detection of, 1194.
—— pentabromonitro-, 983.
—— pentamido-, 247.
—— physical constants of halogen derivatives of, 2.
- test for the hydroxy-derivatives of, 669.
· tetrabromodinitro-, 982.
Benzene triamidodinitro-, 247.
—— trianilidodinitro-, 248.
—— tribromodinitro-, action of ethyl sodacetoacetate on, 772.
—— —— action of ethyl sodiomalonate on, 377.
—— tribromotrinitro-, action of ethyl sodiomalonate on, 497.
—— trisubstituted derivatives of, 884.
Benzeneazobenzylidene-naphthylamine, 616.
Benzeneazodianilidonaphthalene, 629.
Benzeneazodihydroxynaphthalene, [1 : 2 : 2′], 628.
Benzeneazo-α-dinaphthylamine, 912.
Benzeneazo-αβ-dinaphthylamine, 993.
Benzeneazo-αβ-dinaphthylamine, α-, 385.
Benzeneazo-βα-dinaphthylamine, α-, 385.
Benzeneazo-ββ-dinaphthylamine, 993.
Benzeneazodiphenylcarbamide, 616.
Benzeneazoethyl-α-naphthylamine, 911.
Benzeneazo-β-naphthylamine, triazine from, Trans., 329.
Benzeneazo-β-naphthyltolylamine, 99.
Benzeneazoparatolyl-α-naphthylamine, 912.
Benzeneazophenol-α-naphthylamine, 912.
Benzene-derivatives, conversion of pentamethylene-derivatives into, 129.
Benzenediazonitrosophenyltolylamine, 610.
Benzenes, bromonitro-compounds prepared from, 983.
—— chloro-, obtained from anisoïl, 365.
Benzene-series, alteration of compounds of, on exposure to air and light, 1401.
—— —— selenium and oxygen derivatives in the, 34.
Benzenesulphonecyanamide, 501.
Benzenesulphoneorthamidobenzamide and its anhydride, 1289.
Benzenetribenzoic acid, 770.
Benzenylacetoethenylazoxime, 44.
—— paranitro-, 46.
Benzenylamidoxime, action of acetaldehyde and ethyl acetoacetate on, 41.
—— action of aldehydes on 253.
—— action of ethyl chloracetate on, 260.
—— paramido-, 46.
—— paranitro-, 44.
Benzenylamidoximeglycollic acid, 260.
—— anhydride, 260.
Benzenylamidoximeoxalic acid, 259.
Benzenylanilidoxime, reactions of, 43.
Benzenylazoximeisoamenyl, 254.
Benzenylazoximeisobutenyl, 254.
Benzenylazoximemetanitrobenzenyl, metanitro-, 256.

Benzenylazoximemethenylcarboxylic acid, 258.
Benzenylazoximephenylethenyl, 253.
Benzenylazoximepropenyl, 254.
Benzenylazoximesalicenyl, 254.
Benzenylcarbonylimidoxime, paranitro-, 45.
Benzenylethenylazoxime, paranitro-, 45.
Benzenylhydrazoximeamidobenzenylamine, 255.
Benzenylhydrazoximeamidometanitrobenzylidene, metanitro-, 256.
Benzenylhydrazoximeisoamylidene, 254.
Benzenylhydrazoximeisobutylidene, 254.
Benzenylhydrazoximephenylethylidene, 253.
Benzenylhydrazoximepropylidene, 254.
Benzenylhydrazoximesalicidene, 254.
Benzenylorthotoluidoxime, 256.
Benzenylparatoluidoxime, 43.
Benzenylparatoluylcarbonylimidoxime, 43.
Benzhydroxamic acid, constitution of, 256.
Benzidine, 1297.
—— metadiamido-, 782.
—— metadinitro-, 782.
—— metamido-, 783.
—— metanitro-, 783.
Benzidinediurethane, 1298.
Benzidinemetadisulphonic acid, 58.
Benzidinesemiurethane, 1298.
Benzidinesulphone, 59.
Benzidinesulphonedisulphonic acid, 60.
Benzidinesulphonesulphonic acid, 59.
Benzidinesulphonic acid, 57.
Benzidinetetrasulphonic acid, 59.
Benzidinetrisulphonic acid, 58.
Benzile, action of ammonium formate on, 784.
—— chloro-, 783.
—— condensation products of α-acetylpyrroline with, 1000.
—— nitro-, 624.
—— —— dioximes of, 624.
oximes, atomic arrangement in, 349.
· constitution of, 721.
· isomerism of, 575.
—— reduction of, Proc., 1890, 31.
Benzilemetanitrophenylhydrazine, 151.
Benzilemethylphenylhydrazone, 24.
Benzilemethylphenylosazone, 24.
Benzileorthocarboxylic acid, 989.
Benzileparacarboxylic acid, 168.
Benzimido-ethyl ether, metanitro-, 973.
Benzobutyl alcohol, 309.
—— —— oxime, Trans., 310.
Benzoic acid, action of nitrous anhydride on, 1401.
—— —— detection of, in foods, 1031.
Benzoic chloride, action of, on sodium cyanamide, 1253.
—— sulphinide, action of acids on, 94.
Benzoïn, action of ammonium formate on, 784.
—— and acetone, compound from Trans., 783.
Benzoinoxime, a second, 1264.
Benzoparatoluidine, 43.
—— thio-, 43.
Benzophenodihydroketometadiazine, 178.
Benzophenone, derivatives of, 1422.
—— paramido-, 1142.
Benzophenones, halogen, oximes of, 1144.
Benzophenyldihydroketometadiazine, derivatives of, 178.
Benzorthotoluidide, thio-, 256.
Benzoylacetonemethylphenylhydrazone, 24.
Benzoylacetonitrile, 1251.
Benzoyl-β-acetylmetanitrophenylhydrazine, α-, 150.
Benzoylamidocinnamic acid, 623.
Benzoylamido-orthocoumaric acid, 623.
Benzoylanisenylamidoxime, 145.
Benzoylanisoïl, para-, 963.
Benzoylbenzamide, paranitro-, 486.
Benzoylbromallylamine, 953.
Benzoylbromothymol, 366.
Benzoylbutaldehyde, 358.
Benzoylchlorodibromophenol, 1108.
Benzoyl-compounds of carbohydrates, glucosamine, and glucosides, 578.
Benzoylcotarnine, 528.
Benzoylcotarnineoxime, 528.
Benzoylcyanamide, 1253.
Benzoyldihydropyrroline, 65.
—— derivatives of, 1430.
Benzoyldithionaphthol, 1306.
Benzoyleugenol, dibromo-, 638.
Benzoylformaldehyde, preparation of, 51.
Benzoylimidocinnamic acid, Plochl's, 623.
Benzoylimidocoumarin, Plochl's, and its isomerides, 621.
Benzoyl-α-isoamylpropionic acid, β-, 1101.
Benzoylmethylecgonine hydrochloride, 647.
Benzoyl-β-naphthenylamidoxime, 62.
Benzoyl-α-naphthyl ethyl ether, 964.
Benzoyl-β-naphthylhydrazine, 61.
Benzoylparaxylidine, 606.
Benzoylphenetoïl, para-, 964.
Benzoylphenylacetaldehyde, 359.
Benzoylpicolylfurylalkeïne, 1437.
Benzoylpropaldehyde, 358.
Benzoylpropionic acid, 895.
Benzoylpyridyl-β-lactic acid, 521.

Benzoylsaliconylamidoxime, 143.
Benzoyltannin, 163.
Benzoylthio-β-dinaphthylamine, 1306.
Benzyl alcohol, orthamido-, 1254.
—— —— —— derivatives of, 178.
—— —— paranitro-, 486.
—— bisulphide, orthonitro-, 488.
—— cyanide, displacement of the methylene hydrogen atoms in, 1142.
—— imidophenylthiocarbamate, Trans., 296.
—— methyl ketone, bromodinitro-, 773.
—— —— —— trinitro-, 1419.
—— phenylimidophenylthiocarbamate, Trans., 298.
—— sodium thiosulphate, 1419.
—— sulphide, orthonitro-, 487.
—— $\Delta^{2\text{-cistrans}}$ tetrahydroterephthalate, 1134.
—— thiocarbamate, preparation, reactions and properties of, Trans., 293.
Benzylacetamide, orthamido-, 1442.
—— paranitro-, 486.
Benzylacetanilide, orthamido-, 1443.
Benzylacetone, metamido-, 1138.
Benzylacetoparatoluidide, orthamido-, 1258.
Benzylalsorbite, 730.
Benzylamine. action of, on methylene chloride, 887.
—— paranitro-, 486.
Benzylamineparacarboxylic acid, 977.
Benzylangelicalactone, 376.
Benzylaniline, orthamido-, 1258.
—— orthonitro-, reduction of, 1444.
—— paranitroso-, 614.
Benzylanthracene, 1145.
—— dihydride, 1426.
Benzylanthracenesulphonic acid, barium salt of, 1145.
Benzylanthranol, 1425.
Benzylbenzamide, orthamido-, 1442.
—— orthonitro-, 1412.
Benzylbenzoylanilide, orthamido-, 1258.
Benzylcarbamide, paranitro-, 486.
Benzylcyanophenylthiocarbamide, amido-, 1408.
Benzyldeoxybenzoïn, ortho- and para-nitro-, 1142.
—— paramido-, 1143.
Benzyldihydroanthranol, 1425.
Benzyldihydropyrroline, 65, 1430.
Benzyleneanthrone, amido-, 1425.
Benzylethanetricarboxylic acid, 896.
Benzylethylmetamidophenol hydrochloride, orthonitro-, 1116.
—— orthamido-, 1116.
Benzylformamide, orthonitro-, 1443.
Benzylformanilide, orthonitro-, 72.
Benzylformorthotoluide, orthonitro-, 74.
Benzylformoparatoluidide, orthonitro-, 73.
Benzylfurfuraldoxime, 1267.
Benzylfurfuryl, 1407.
Benzyl-γ-hydroxyvaleric acid, β-, 377.
Benzylideneamidophenyltolylamine, 610.
—— paranitro-, 610.
Benzylidenebenzidine, metanitro-, 1298.
Benzylidenechloroparatolylsulphone, 380.
Benzylidenechlorophenylsulphone, 379.
Benzylidenediethylsulphone, 56.
Benzylidenelepidineparasulphonic acid, 1435.
Benzylidenemetanitrophenylhydrazine, 150.
Benzylideneorthamidoazotoluene, 616.
Benzylideneorthonitrophenylhydrazine, 148.
Benzylideneparamidodiphenylamine, 609.
Benzylideneparaxylidene, 606.
Benzylidenepseudocumylhydrazine, Trans., 55.
Benzylidenequinoline - 3 - carboxylic acid, 1325.
Benzylidenetetrahydro - β - naphthylamine, ac.-, 632.
Benzylidenexylidine, metanitro-, 606.
Benzylisoanisaldoxime, 1261.
Benzylisobenzaldoxime, 1123.
—— and phenyl cyanate, interaction of, 1412.
—— paranitro-, modifications of, 1412.
Benzyllevulinic acid, 376.
—— —— bromo-, 376.
Benzylmetanitroisobenzaldoxime, 1262.
Benzylmethylcarboxyglutaric acid, 1135.
Benzylmethylsuccinic acid, 1134.
—— anhydride, 774.
Benzyloxanthranol, 1144, 1425.
Benzylparamidodiphenylamine, 609.
Benzylparatoluidine, orthamido-, 1258.
Benzylparaxylidine, 606.
Benzylphenylsulphone, 380.
Benzylphosphines and their derivatives, 766.
Benzylphosphinic acid, 766.
Benzylphosphinous acid, 766.
Benzylphthalimidine, paramido-, 487.
Benzylpyridyl chloride, action of moist silver oxide on, 794.
—— platinochloride, 794.
Benzylsuccinic acid, 774, 895, 1135.
—— —— homologues of, 774.
—— anhydride, 896.
Benzylthiosulphuric acid, 1419.
Benzylvalerolactone, 376.
Berberal, Trans., 1062.
—— action of alkalis on, Trans., 1075.
—— action of phenylhydrazine on, Trans., 1077.
—— constitution of, Trans., 1002.
—— examination of, Trans., 1000.

Berberal, hydrolysis of, Trans., 1064.
—— synthesis of, Trans., 1079.
Berberilic acid, Trans., 994, 1018.
—— —— action of heat on, Trans., 1051.
—— —— constitution of, Trans., 998.
—— —— hydrolysis of, Trans., 1053.
—— —— salts of, Trans., 1049.
Berberine, 1011, Trans., 992.
—— constitution of, Trans., 1003.
—— hydrobromide, tetrabromo-, 1012.
—— hydrogen sulphite, Trans., 1096.
—— oxidation of, with potassium permanganate, Trans., 1010.
Berberis alkaloids, 648.
Berberoline, constitution of, Trans., 1009.
Berilic acid, Trans., 1091.
—— —— salts of, Trans., 1092.
Berthollet's laws, 1367.
Beryllium antimonate, 216.
—— atomic weight of, 698, 1375.
—— fluoride, heat of neutralisation of, 680.
—— oxide, action of magnesium on, 451.
—— —— preparation and properties of, 697.
—— phosphates, 1056.
—— sodium silicates, 562.
Betaines of pyridine bases, 1431.
—— preparation of, 747.
Betel leaves, ethereal oil of, 135.
Bidioxymethyleneindigo, 1140.
Bile, urobilin in the, 187.
Bile-pigments, 181.
Bilirubin, molecular weight of, 76.
—— oxidation of, 181.
Biliverdin, reduction of, 181.
Birch oil, 256.
Bismuth, atomic weight of, 706.
—— behaviour of, with sulphur and selenium, 216.
—— effect of, on the freezing point of tin, Trans., 384.
—— electrolytic estimation of, 295.
—— electrolytic separation of, from copper, 1029.
—— phosphorescence of, in the sulphides of the alkaline earth metals, 201.
—— physical properties of, 707.
—— potassium iodides, 708, 1067.
—— separation of, from lead, 421.
—— sulphide, precipitated, composition of, 1217.
Bis-1-phenyl-3-methyl-4-methylene-5-pyrazolone, Trans., 222.
Blacking, boot-, analysis of, 1478.
Bleaching powder, gas-volumetric estimation of, 1469.
Blende containing manganese, estimation of zinc in, 827.
Blood, arterial and venous, the difference between in different blood vessels, 808.
—— carbonic oxide, detection of, 1200.
—— destruction of glucose by, 1172.
—— estimation of iron in, 297.
—— heat developed by the action of oxygen on the, 274.
—— influence of salts on the clotting of, 1176.
—— method of raising the specific gravity of, 393.
—— of the Aplysiæ, 810.
—— oxidation in the, 651.
—— permeability of the red corpuscles of, in relation to their isotonic coefficients, 809.
—— proportion of, to body weight, 1015.
—— stains, detection of, 840.
—— sugar in the, 276.
Blood-corpuscles, red, lecithin and cholesterin in, 1017.
Blood-fibrin, heat of combustion of, 938.
Blood-plasma of the splenic vein, is free hæmoglobin present in ?, 1016.
Blue, Egyptian, 215.
—— fluorescent, 157.
—— non-fluorescent, 156.
Body-weight, proportion of blood to, 1015.
Boiler scale, composition of, 944.
Boiling points, law of, 1043.
—— —— of substances are a function of their chemical nature, 941, 1364.
Bootblacking, analysis of, 1478.
Boracite, artificial production of, in the wet way, 1384.
Boric acid, behaviour of mannitol towards, 1357.
—— —— in the beech, 656.
—— and phosphoric acids, a derivative of, 108.
—— anhydride, action of magnesium on, 693.
Borneol, action of carbon bisulphide on, 517.
—— preparation of, from terpene, Trans., 963.
—— specific volume of, 169.
Borneols, α-, camphorates of, 790.
Bornite, mineral related to, from Montana, 710.
Bornyl phenylcarbamates, 518.
Bornylxanthic acid, 517.
Boron chloride, combination of ammonia and hydrogen phosphide with, 690.
—— fluoride, combination of, with hydrogen phosphide, 448.
—— hydrides of, 693.
—— influence of, on steel, 566.

Boron, occurrence of, in plants, and its physiological meaning, 1338.
—— preparation of, 331.
Botryogen, 456.
Bouquet of fermented liquids, 1180.
—— of wines, influence of yeast on, 281.
Bournonite from Arizona, 572.
Brandy, analyses of, 1195.
—— from different parts of the German Empire, amyl alcohol in, 1388.
Braunite from Örebrö, 1076.
Brazileïn, tribromo-, 997.
Brazileïndihydroxime, 997.
Brazileïnphenylhydrazone, 997.
Brazilin, 996.
—— tetramethyl ether, bromine derivatives of, 997.
Bromides, iodides, and chlorides of the alkalis, distinction between, 289.
Bromine, volumetric estimation of, in the presence of chlorine and iodine, 824.
Bromo-derivatives of the paraffins, formation of, from alcohols, 465.
Bromoformberberine, 1012.
Brucine, bromination of, 1330.
—— dichloro-, 1330.
—— ferrocyanide, 1318.
Brucite from the Tyrol, 339.
Burners, new, 106.
Butaldehyde and succinic acid, condensation of, 588.
Butaldehydes, condensation of phenylenediamines with, 138.
Butter, analysis of, 838.
—— estimation of soluble and insoluble fatty acids in, 93.
—— examination of, 305.
—— volatile fatty acids of, 186.
Butyl β-ethoxyquartenylate, 866.
—— β-isobutoxyquartenylate, 866.
—— mercaptan, tertiary, Trans., 639.
—— β-methoxyquartenylate, 866.
—— nitrites, normal and secondary, 353.
—— β-propoxyquartenylate, 866.
Butylbenzenesulphonic acid, para-tertiary, 1296.
Butylcarbinol, tertiary, 1388.
Butylphenol, para-tertiary, 1296.
Butylsuccinic acid, 872.
Butyric acid, γ-amido-, 360.
—— —— detection and estimation of, in wines, in the presence of acetic acid, 1344.
—— acids, electrolysis of, 1237.
Butyrolactonedicarboxylic acid, βγ-, 587.
Butyronitrile, γ-bromo-, 360.
—— γ-chloro-, 1221.

C.

Cacoclasite not a distinct species, 457.
Cadmium, action of, on the halogen salts of cadmium, 1376.
—— antimonate, 216.
—— apatites, chlor-, and brom-, 11.
—— arsenate, 563.
—— arsenates, 11.
—— arsenoapatite, chlor- and brom-, 11.
—— double thiosulphates of, 1057.
—— effect of, on the freezing point of tin, Trans., 383.
—— electrolytic estimation of, 294.
—— electrolytic separation of, from aluminium, chromium, iron, nickel, and zinc, 1028.
—— electrolytic separation of, from arsenic, molybdenum, and tungsten, 1029.
—— electrolytic separation of, from cobalt and nickel, 664.
—— oxide, action of magnesium on, 452.
—— phosphates, 11.
—— potassium arsenate, 563.
—— salts, electrical conductivity of solutions of, 1203.
—— separation of copper from, 295.
—— sodium arsenate, 563.
—— —— thiosulphates, 12.
—— sub-hydroxide, 1376.
—— sub-oxide, 1376.
—— thiosulphate, 12, 564.
Cadmous hydroxide, 1376.
—— oxide, 1376.
Cæsium carbonate, reduction of, by magnesium, 333.
Cakes, feeding, relative values of, 395.
Calamine, estimation of zinc in, 418.
—— from the United States, 118.
Calciothorite, 1079.
Calcium carbonate, secretion of, by animals, 653.
—— —— solubility of, in fresh and sea water, 450.
—— effect of, on the freezing point of tin, Trans., 384.
—— estimation of, in presence of phosphoric acid, iron, aluminium, and manganese, 417.
—— hydrogen phosphate, presence of magnesium in, 664.
—— oxalate, formation of, in plants, 191.
—— oxide, action of magnesium on, 451.
—— —— influence of, on the decomposition of potassium chlorate, Trans., 280.
—— phosphide, preparation of, 942.

Calcium plumbate, 561.
—— tetrahydrogen phosphate, 695.
Callose, a new fundamental substance in vegetable membrane, 734.
Calomel, action of hydrocyanic acid on, 223.
Calorimeter, mixing, new form of, 440.
Calycanthine, 403.
Calycanthus glaucus, analysis of the seed of, 403.
Camphamines, 516.
Camphene, constitution of, Trans., 964.
—— glycol, 1313.
Camphonitrophenol, acetyl and ethyl derivatives of, 63.
—— benzoate, 64.
—— phosphate, 63.
—— phthalate, 64.
Camphor, a new monobromo-, Trans., 828.
—— action of ethyl oxalate on, Trans., 652.
—— an isomeride of, 169.
—— compounds of, with phenols, 1427.
—— constitution of, Trans., 832, 964.
—— distillation of, with zinc chloride, 1248.
—— isobromo-, Trans., 828.
—— new bases derived from, 516.
—— β-nitro- and α-chloronitro-, constitution of, 515.
—— oil of, 261.
—— phenolsulphonic acids from, 791.
—— production of, from turpentine, Trans., 961.
—— rotatory power of, when dissolved in various oils, 1427.
—— specific volume of, 169.
Camphoraldehyde, constitution of, 359.
Camphorates of the α-borneols, 790.
Camphoric acid, constitution of, 517.
—— acids, 790, 995.
Camphoroxalic acid, Trans., 653.
—— —— reduction of, Trans., 654.
Camphorsulphonic acid, bromo-, Trans., 833.
Camphoryl chloride, chloro-, 995.
Camphoryldiamide, 1151.
Camphorylimide, 1152.
Cantharidin, derivatives of, 640.
—— phenylhydrazone, 640.
Capillarity, influence of, on the solvent action of liquids, 555.
Capillary tubes, rise of solutions in, 684.
Capric chloride, 1252.
Caprolactone, action of sodium ethoxide on, 868.
Caprylic chloride, 1252.
Caraway, oil of, Norwegian, 902.
Carbamide chlorides, aromatic, 633.
—— condensation of, with ethyl acetoacetate, 1240.
Carbamide, conversion of thiocarbamide into, 1399.
—— estimation of, 308.
—— heats of formation and combustion of, 206.
—— See also Urea.
Carbanilamidocresol, 248.
Carbanilamidocumenol, 249.
Carbanilamidonaphthol, 248.
Carbanilamido-α-naphthol, 249.
Carbanilamidophenanthrol, 249.
Carbanildiamidoresorcinol, 249.
Carbanilidoacetophenoneoxime, 251.
Carbanilidoacetoxime, 251.
Carbanilidoamidoazobenzene, 616.
Carbanilidoamidoazotoluene, 616.
Carbanilidoanisaldoxime, 251.
Carbanilidobenzaldoxime, 251.
Carbanilidobenzeneazo-β-naphthylamine, 616.
Carbanilido-α-benzilmonoxime, 252.
Carbanilido-γ-benzilmonoxime, 252.
Carbanilidobenzophenoneoxime, 251.
Carbanilidocamphoroxime, 251.
Carbanilidocarvoxime, 251.
Carbanilidofurfuraldoxime, 251.
Carbanilidohydroxyazobenzene, 614.
Carbanilidohydroxyhydrazobenzene, 615.
Carbanilidoisoanisaldoxime, 1261.
Carbanilidoisobenzaldoxime, 253.
Carbanilidoisocuminaldoxime, 1263.
Carbanilidoisonitrosobutyl methyl ketone, 252.
Carbanilidometanitrobenzaldoxime, 1262.
Carbanilidometanitroisobenzaldoxime, 1262.
Carbanilidomethylpropylglyoxime, 252.
Carbanilido-α-naphthaquinoneoxime, 252.
Carbanilido-β-naphthaquinone-α-oxime, 252.
Carbanilido-β-naphthaquinone-β-oxime, 252.
Carbanilido-orthanisaldoxime, 1111.
Carbanilidophenoldisazobenzene, 615.
Carbanilidoquinoneoxime, 252.
Carbanilidothymoquinoneoxime, 252.
Carbazoledisulphonic acid, 1297.
Carbizines, constitution of, 1440.
Carbodiamidoresorcinol, thio-, 249.
Carbodiimides and orthodiamines, condensation products of, 246.
Carbodiphenyline, 167.
Carbohydrate from *Stachys tuberifera*, 1088.
Carbohydrates, 1085.
—— action of the bacillus of malignant œdema on, 1454.
—— colloid, method of separation of, 122.

Carbohydrates, colloid, precipitation of, by salts, 122.
—— in peach gum, 1022.
—— in the seeds of *Phaseolus vulgaris*, 917.
—— of the sweet potato, 1022.
—— soluble, in the seeds of legumes, 917.
—— sugar yielding, insoluble, in seeds, 541.
Carbolic acid, commercial, examination of, 300.
Carbon, action of fluorine on different forms of, 557.
—— and soda or potash, use of, in analysis, 1027.
—— and sulphur, simultaneous estimation of, 2900.
—— as an impurity affecting the estimation of the atomic weight of hydrogen, 1369.
—— assimilation of, by green plants, 818
—— bisulphide, explosion of, with air or oxygen, Trans., 625.
—— —— heats of combustion and formation of, 1361.
—— estimation of, in graphite, 923.
—— estimation of, in organic substances in the wet way, 1467.
—— fluorides, hydrates of, 1386.
—— —— preparation of, 558.
—— free and combined, estimation of, in iron and steel, 1027.
—— graphitic, different forms of, and their derivatives, 448.
—— tetrafluoride, 944, 1053.
—— volumetric estimation of, in iron, 924.
Carbon-acids, bibasic, new synthesis of, 583.
Carbon-atoms, limitation of the free rotation of singly bound, 723.
Carbon-chains, closed, synthesis of substances containing, 877.
Carbon compounds, action of ammoniacal cupric oxide on, 21.
—— —— arrangement in space of the atoms in the molecule of, containing nitrogen, 348.
—— —— chemical constitution of, and the sign and variations of their rotatory power, 722.
—— —— dispersion of, 1353.
—— —— oxidation of the sulphur in, 1462.
Carbonates, hydrogen, electrolysis of, 1204.
—— rate of solution of, in acids, 843.
—— volumetric estimation of, 417.
Carbonic anhydride, density of, 322.
—— —— estimation of, 1188.
Carbonic anhydride, estimation of, in air, 1188.
—— —— estimation of, in potable waters containing magnesium, 197.
—— —— estimation of, in salts, 417.
—— —— formed in manured and unmanured soils, 408.
—— —— improvement in the method of estimating by volume, 194.
—— —— influence of muscular work, hunger, and temperature on the exhalation of, 1334.
—— —— influence of, on the products of fermentation, 281.
—— —— reduction of, by magnesium, 1372.
—— oxide, action of, on nickel, Trans., 749.
—— —— condensation of, under the influence of the silent discharge, 691, 692.
—— —— detector, 194.
—— —— effect of the silent discharge on, 1358.
—— —— reduction of, by magnesium, 1373.
—— —— solubility of, in mixtures of alcohol and water, 103.
Carbonic-oxide-hæmoglobin, detection of, 432, 1200.
Carbonyldiparanitrobenzenylamidoxime, 45.
Carbonylhydroferrocyanic acid and its derivatives, 116.
Carbonylorthamidophenol, changes of, in the animal system, 1413.
—— constitution of, 1413.
Carbonylorthohydroxyamidophenol, 1413.
Carboxybenzylphthalamic acid, para-, 977.
Carboxycinnamic acid, ortho-, oxidation of, 54.
Carboxycinnamyldithiocarbamic acid, ortho-, 1123.
Carboxyl-group in the aromatic series, influence of certain groups on the thermochemical value of, 439.
Carminic acid, constitution of the hydrocarbon obtained from, 1145.
Carrotene, 641.
—— in *Diaptomus*, 640.
—— in leaves, 285.
Carvacrol, bromamido-, constitution of, 884.
—— bromonitroso-, constitution of, 884
Casein, estimation of, 312.
—— estimation of, in condensed milk, 92.
—— heat of combustion of, 938.
Cassia, oil of, examination of, 423.

Castor-oil bean, poisonous principle of, 535.
—— examination of, 429.
Catechol, action of chlorine on, 754, 1255.
—— physiological action of, 1019.
—— preparation of, Trans., 587.
Cattle marrow, 1172.
Celestine from Mineral Co., West Virginia, 1071.
—— occurrence of, near Torda, 713.
Celestine-bed of Koppánd, mean composition of, 713.
Cell, vegetable, behaviour of, with alkaline silver solution, 401.
Cell. See Voltaic.
Cell-membrane, vegetable, composition of, 1456.
Cell-membranes, vegetable, 283.
Cellulose, acetylation of, Trans., 1.
—— and its modifications, 581.
—— animal, 227.
—— constitution of, Trans., 4.
—— estimation of, 303.
—— existance of an enzyme in the seeds of grasses which dissolves, Trans., 497.
—— flax, characters of, Trans., 199.
—— from various sources, 1457.
—— pentacetate, Trans., 2.
Celtis reticulosa, scatole in the wood of, 191.
Cephalanthin, 171.
Cerebrose, identity of, with galactose, 121, Trans., 57.
Ceresin, detection of, in beeswax, 421.
Cerium earths, 851.
—— hydrogen sulphate, 452.
—— phosphate, from South Norway, 111.
Cerotic acid, oxidation of, by nitric acid, 1237.
Ceryl alcohol from flax, Trans., 198.
Cetraric acid, 600.
Chalcedony, expansion of, 1372.
Champignons du muguet, alcoholic fermentation and conversion of alcohol into aldehyde by, 1179.
Charcoal, oxidising and decolorising properties of, 690.
Chavicol, properties and derivatives of, 135.
Chelidonine, reactions of, 310.
Chemical change, rate of, 327.
—— —— under great pressure, evidence of, afforded by petrographical research, Trans., 404.
—— energy, increase of, at the free surface of liquids, 328.
—— equilibrium between hydrogen chloride and hydrogen in conjunction with metals, 685.
Chemical equilibrium, rôle of solid substances in, 1365.
—— reactions, the dead space in, 1207.
Chinine, formation of lepidine derivatives from, 1433.
Chitin, heat of combustion of, 938.
Chloral, action of sulphides on, 291.
—— and succinic acid, condensation of, 586.
Chloral-ammonia, action of heat on, 230.
Chloralide, action of phosphoric chloride on, 27.
Chloralimide, 230.
—— and its isomeride, 1093.
Chloranilic acid, decomposition products of, 130.
Chloranil, action of sodium thiosulphate on, 1419.
Chloric acid, action of light on, Trans., 624.
Chlorides, bromides, and iodides of the alkalis, distinction between, 289.
—— hydrochlorides of, 106.
Chlorine, action of water in the light on, Trans., 613.
—— and hydrogen chloride, estimation of, when mixed, 412.
—— and crystalline sodium carbonate, direct production of, from sodium chloride, 10.
—— direct estimation of, in mixtures of chlorides and iodides, 920.
—— estimation of, in water, 86.
—— free, detection of, in hydrochloric acid, 289, 547.
—— gas, preparation of, for laboratory purposes, 415.
—— importance of, in the plant, 1182.
—— oxygen and hydrogen, equilibrium between, 8.
—— preparation of, in a Kipp's apparatus, 6.
—— rapid detection and estimation of, in alkaline thiocyanates, 663.
Chlorine-water, rate of decomposition of, by light, 849.
Chloroform, action of sulphides on, 291.
Chloroformamide-synthesis, a modification of, 974.
Chloroformberberine, 1012.
Chlorophyll, colouring matters of, 171.
—— estimation of, in leaves and in extracts, 672.
—— relation between the assimilation and transpiration produced by, 190.
Chlorophyll-grains, green colouring matter of, 641.
Cholesterin, higher homologue of, 757.
—— in plants, 1457.
—— in red blood corpuscles, 1017.
—— molecular weight of, 914.

Cholesterin propionate, 932.
—— reaction of, 932.
Cholesterol, occurrence of, in *Scopolia carniolica*, 403.
Cholestol reaction, 1474.
Cholic acid, molecular weight of, 914.
Chondrin, heat of combustion of, 938.
Chondrus crispus, iodine in, 402.
Chromates, double, 1065.
Chrome iron, 568.
—— —— ore, analysis of, 828, 1027.
—— —— —— volumetric estimation of chromium in, 298.
Chromic bromide, isomeric forms of, 1063.
Chromiodates, 1378.
Chromite, artificial preparation of, 568
Chromium bases, constitution of, 1213.
—— electrolytic estimations with, 294.
—— estimation of, in foods, 195.
—— estimation of, in iron and steel, 85.
—— oxide, influence of, on the decomposition of potassium chlorate, Trans., 277,
—— potassium arsenate, 1378.
—— pyroarsenate, 1378.
—— sodium arsenate, 1378.
—— —— sulphide, 215.
—— volumetric estimation of, in chrome iron ore, 298.
Chrysanthemum cinerariæfolium, homologue of, cholesterin from, 757.
Chrysene, 1312.
—— amido-, 789, 902, 1313.
—— synthesis of, 515.
Chrysenic acid, 1312 .
Chrysoketone, 1312.
Chrysoquinone, preparation of, 1312.
Chrystobalite, 1071.
Chyle, destruction of glucose by, 1172.
—— human, 394.
—— presence in, of a ferment which destroys sugar, 810.
—— sugar in the, 276.
Cinchine, formation of lepidine derivatives from, 1433.
Cinchomeronamic acid, 1157.
Cinchomerondianilide, 1158.
Cinchomeronimide, 1157.
Cinchomeronphenylphenylimide, 1158.
Cinchona alkaloids, estimation of, 309.
Cinchonic acid, sulpho-, 1435.
Cinchonidine ferrocyanide, 1318.
—— melting point of, 1166.
Cinchonine ferrocyanide, 1318.
Cineole, constitution of, 1315.
Cineolic acid, constitution of, 1315.
—— anhydride, 1314.
Cinnamaldehyde, action of ethyl acetoacetate on, 768.
—— and ammonia, action of, on diacetyl, and on phenanthraquinone, Trans., 11.
Cinnamaldehyde, orthonitro-, action of, on malonic acid, 163.
—— paranitro-, derivatives of, 161.
Cinnamaldoxime, paranitro-, 161.
Cinnamenylacrylic acid, oxidation of, 1274.
Cinnamenylcinchonic acid, α-, 176.
Cinnamenyldimethylglyoxaline, Trans., 11.
Cinnamenyldiphenyleneoxazole, Trans., 12.
Cinnamenyl-α-naphthacinchonic acid, α-, 1007.
Cinnamenyl-β-naphthacinchonic acid, α-, 1008.
Cinnamenyl α-naphthaquinoline, α-, 1008.
Cinnamenyl-β-naphthaquinoline, α-, 1009.
Cinnamic acid, amido-, derivatives of, 1123.
—— —— and its homologues, preparation of, 891.
—— —— benzoyllactimide of, 624.
—— —— preparation of, 892.
—— and isocinnamic acids, nature of the isomerism of, 495.
Cinnamolmetatoluylenediamine, 139.
Cinnamon oil, examination of, 423.
Cinnamylcocaïne from coca leaves, 76.
—— occurring naturally in, 390.
Cinnamylidenetolidine, 1299.
Cinnamylindole, [3′], 989.
Citraconanil, 1102.
—— and pyranilpyroïnlactone, identity of, 774.
Citraconic acid, action of aniline on, 368.
—— —— synthesis of, from ethyl propenyltricarboxylate, 1101.
Citrates, distillation products of, 1102.
Citrazinimide, consitution of, 736.
Citric acid, estimation of, in lemon juice, 88.
—— —— thermochemistry of, 101.
Citronella oil, 231.
Citronellic aldehyde, 231.
Citronellyl alcohol, 231.
Citrus, crystalline substances from the fruits of various species of, Trans., 323.
Clark cell, standard, 202.
Clark's soap test, standard solution for, 198.
Clays, composition of, 1060.
Clotting, influence of salts on, 1176,
Clover, red, yields and composition of a variety of, 1183.
Coagulation of blood, &c., influence of salts on, 1176.
Coal, occurrence and estimation of sulphur in, 414.
Coal-tar, coumarone in, 496.

Coal-tar, products of the distillation of, 463.
Cobalt, anomalous rotatory dispersion in, 673.
—— antimonate, 216.
—— arsenate, 563.
—— bases, constitution of, 1213.
—— carbonylferrocyanide, 117.
—— chromiodate, 1378.
—— electrolytic estimation of, 294.
—— electrolytic separation of cadmium, of mercury, of silver from, 664.
—— estimation of, 1470.
—— oxides, 1213.
—— potassium arsenate, 564.
—— salts, action of sodium carbonate and bromine on solutions of, 568.
—— —— effect of temperature on the magnetism of, 678.
—— sesquioxide, influence of, on the decomposition of potassium chlorate, Trans., 278.
—— sodium arsenates, 564.
—— —— sulphide, 215.
—— —— thiosulphate, 12.
—— thiosulphate, 330.
Cobaltammonium bases, constitution of, 953.
—— salts, mercury derivatives of, 13.
—— sulphites, 14.
Cobaltoctamine salts, 14.
Coca leaves, cinnamylcocaïne occurring naturally in, 390.
—— —— estimation of alkaloïds in, 310.
Cocaïne and atropine, relation between, 1010.
—— bye-product from the commercial synthesis of, 647, 803.
—— chromate, 839.
—— crude, from Peru, valuation of, 838.
—— ferrocyanide, 1318.
—— hydrochloride, detection of, 96.
—— occurrence of isocinnamic acid in the alkaloïds of, 494.
—— test for, 839.
Codeïne, estimation of, 1198.
—— methiodide, 179.
—— reaction of, 311.
Coffee, Mussoenda seeds as a substitute for, 285.
Cognac, adulterations of, 1196.
Colloidal substances, behaviour of, with reference to Raoult's law, 105.
—— —— molecular weights of, 725.
Colloïds, cryoscopical investigation of, 1215.
—— freezing of solutions of, 685.
Colour analysis by means of the tintometer, 1461.
Colouring matter from *Diaptomus* analogous to carrotene, 640.
Colouring matters of wines, 311.
—— —— spectroscopic method for the estimation of, 1476.
Combustion, formation of ozone and nitrogen acids in, 447.
—— rapid, formation of ozone during, 330.
Combustion with lead chromate, 926
Combustions under a high pressure, 1050.
Composites, inulin in the capitula of, 191.
Conductivity, electrical, as a means of investigating the interaction of acids of complex function, 204.
—— —— change of, in freshly prepared solutions, 204.
—— —— of air due to the formation of ozone, 676.
—— —— of aspartic acid, 204.
—— —— of distilled water, 1357.
—— —— of fused and solid salts, 1037.
—— —— of hydrogen chloride in different solvents, 97.
—— —— of phenols and hydroxybenzoic acids, 677.
—— —— of solid mercury, 98.
—— —— of some salt solutions between 18° and 100°, 676.
—— —— of solutions of boric acid containing mannitol, 1357.
—— —— of solutions of cadmium salts, 1203.
—— —— of sulphuric acid solutions, Trans., 86–88, 158–160.
—— —— of the ammonium and aniline salts of the hydroxybenzoic acids, 1039.
—— —— of the substituted succinic and glutaric acids, 1038.
Conhydrine, attempt to synthesise, 1447.
Coniceïne, γ-, 802.
Coniceïnes, 1328.
Coniine, 802.
—— ferrocyanide, 1318.
Constitution of organic substances, relation of the heat of combustion to, 1206.
Conyrine, 802.
Copiapite, 454, 456.
Copper, analysis of organic substances containing, 296.
—— and ferro-manganese, electrical resistance of, 1356.
—— and nitric acid, conditions of the reaction between, 701.
—— and potassium chlorides, saturated solutions of compounds of, 564.
—— and zinc sulphates, electrolysis of mixed aqueous solutions of, 678.
—— antimonate, 216.
—— double phosphates, [illegible].

Copper carbonylferrocyanide, 117.
—— chloride solutions, thermal behaviour of, 1206.
—— chromiodate, 1379.
—— effect of, on the freezing point of tin, Trans., 379.
—— electrolytic estimation of, 294.
—— electrolytic separation of, from arsenic, 1029.
—— electrolytic separation of, from cadmium, 665.
—— electrolytic separation of, from iron, aluminium, cadmium, chromium, cobalt, nickel, iron, or zinc, 1028.
—— estimation of, 665.
—— estimation of, by titration with potassium cyanide, 547.
—— estimation of, in iron and steel, 85.
—— evidence of the occurrence of a new element in, 434.
—— hydrosulphide, Proc., 1890, 50.
—— influence of, on steel, 567.
—— lead and tin, alloy of, 335.
—— native, pseudomorphs of, after azurite, 453.
—— nitrate, crystallised basic, 1376.
—— —— crystallised basic, identical with gerhardite, 714.
—— ores, tourmaline-bearing, from Chili, 114.
—— oxide, behaviour of, at high temperatures, Trans., 269.
—— —— influence of, on the decomposition of potassium chlorate, Trans., 279.
—— oxides, reduction of, by magnesium, 333.
—— oxychlorides, 1058.
—— oxysulphides, 1211.
—— phosphorescence of, in the sulphides of the alkaline earth metals, 201.
—— precipitate formed in ordinary water, 851.
—— precipitation of, as thiocyanate, in assaying, 547.
—— potassium carbonate solution, estimation of sugars with, 1031.
—— pure, production of, in a crystalline condition, Proc., 1890, 95.
—— salts, action of, on metallic cyanides, 464.
—— separation of, from cadmium, 295.
—— sulphate, tetrabasic, 851.
—— sulphide, precipitated, composition of, 1217.
—— volumetric estimation of, 665, 926.
Copper. See also Cuprous.
Copper-bismuth-glance, artificial, 337.
Coquimbite, 454.
Corn cockle seeds, poison of, 1458.
Corpuscles, red, lecithin and cholesterin in, 1017.
—— permeability of, in relation to their isotonic coefficients, 809.
Corundum in Patrick Co., Virginia, 570.
—— synthesis of, 112.
Cossaite from the Upper Susa Valley, 344.
Cotarnelactone, 529.
Cotarnelactonic acid, 529.
Cotarnic acid, 529.
Cotarnine, constitution of, 530.
—— oxime, 528.
Cotarnmethine methochloride, 528.
Cotarnonenitrile, 528.
Cotton-seed oil, detection of, in fats and olive oil, 930.
—— —— estimation of, in lard, 307.
—— —— testing lard for, 428.
—— thermochemistry of, 939.
Coumaric acid, α-benzoyllactimide of, 624.
Coumarinpropionic acid, 584, 777.
Coumarins, thio-, and their behaviour towards hydroxylamine and phenylhydrazine, 624.
Coumarone, bromo-, 496.
—— chloro-, 496.
—— dibromide, 496.
—— dichloride, 496.
—— in coal-tar, 496.
Cow, relative value of various foods for the, 395.
Cranberry juice, fermentation and composition of, 1455.
Crataegus oxyacantha, calcium oxalate in leaves of, 191.
Cresol, crude, examination of, 425.
Cresolbenzein, ortho-, 897.
Cresolglycollic acid, ortho-, 375.
Cresols, condensation of dichlorether with, 1140.
—— physiological action of the three, 813.
Cresyl orthosulphide, 1420.
Cresylethylsulphine, ortho-, 1420.
Cresylsulphone, ortho-, 1420.
Critical atomic coefficients, 414.
—— points, molecular constitution of compounds at their, 413.
Crotonic acid, molecular weight of, 737.
—— acids, thio-derivatives of, 361.
Crotylpyridine, 1436.
Cryohydrates, nature of, Trans., 361.
Cryoscopic investigation of colloids, 1215.
—— method of determining molecular weights, 324.
Crystallisation, apparatus for, at low

temperature and in absence of moisture and air, 1043.
Crystallography of dibenzoylcinnamene-derivatives, TRANS., 714.
Crystals, fluid, 106.
Cuminildioximes, isomeric, 1143.
Cuminolmetatoluylenediamine, 139.
Cumylidenebenzidine, 1298.
Cumylidenetolidine, 1299.
Cupric. See Copper.
Cuprous chloride, influence of hydrogen chloride on the solubility of, 109.
Cupules of the beech, amount of mineral matter and manurial value of, 287.
Cyanacetone, the so-called, 1094, 1095.
Cyanalkines, 1158.
Cyanamide, constitution of the derivatives of, 1222.
Cyanamines, a new class of dyes, 1307.
Cyanethine, formation of, 1158, 1159.
Cyanides, metallic action of cupric salts on, 464
Cyanobenzyl chloride, ortho-, 1249.
—— —— para-, 239.
—— —— para-, derivatives of, 977.
—— cyanide, ortho-, action of hydroxylamine on, 146.
—— —— para-, 239.
—— mercaptan, ortho-, 1250.
—— phthalimide, para-, 977.
—— thiocyanate, ortho-, 1249.
Cyanodiphenylsuccinic acid, 504.
Cyanogen disulphydrate, 29.
—— iodide, vapour density and melting point of, 949.
—— monosulphydrate, 351.
Cyanomethine, formation of, 1158, 1159.
Cyanoparatoluamide, ω-, 239.
Cyanoparatoluic acid, ω-, 240.
Cyanophenylacetamide, para-, 239.
Cyanophenylacetic acid, para-, 239.
Cyanophenylethenylamidoxime, para-, 147.
Cyanophenylethenylazoximebenzenyl, 148.
Cyanopropine, formation of, 1159.
Cyanopropylphthalimide, γ-, 360.
Cyanuric acid, synthesis of, 1082.
Cymene, action of chromyl chloride on, 978, 1254.
—— chloro-, action of sulphonic chloride on, 1288.
—— dibromo-, 366.
—— dinitramido- and dinitro-, constitution of, 753.
Cymenesulphonamide, nitro-α-, 1287.
Cymenesulphonic acid, amido-α-, 1287.
—— —— chloro-, 779.
—— —— chloro- and bromo-α, 1288.
—— —— chloronitro-, 780.
—— —— nitro-α-, 1287.
Cymyl methyl ketone, ortho-, 770.
Cystin in the urine, 1018.
Cystinuria, 189.

D.

Dahllite from Norway, 714.
Damascenine, 1317.
Daturic acid, 1396.
Dead space in chemical reactions, 1207.
Decahydroquinoline and its derivatives, 1319.
Decahydroquinolyl dithiocarbamate, 1319.
Decamethylenedicarboxylic acid, 1237.
Decylene, 594.
Dehydroerythrol, 730.
Dehydrobenzyloxanthranol, 1144.
—— bromide, 1144.
—— bromo-, 1145.
Dehydrodiacetyllevulinic acid, action of ammonia on, 864.
—— —— preparation of, 864.
Dehydrofichtelite, 385.
Dejections, influence of the pancreatic juice on the colour of, 397.
Delvauxite, from Vysočany, Bohemia, 715.
Densities, gas, new method of determining, 321.
—— of sulphuric acid solutions, TRANS., 69–85, 139–158.
Deoxybenzoïn, derivatives of, 1143.
—— displacement of the methylene hydrogen atoms in, 1142.
Deoxybenzoïnorthimidodicarboxylic acid, 1143.
Deoxybenzoïnorthodicarboxylic acid, 1143.
—— anhydride, 1143.
Deoxybenzoïnparacarboxylic acid, dibromo-, 168.
Deoxyfuroïn, 1245.
Desaurines, molecular weight of, 1144.
Descloizite from American localities, 341.
Desmine from the French Creek Mines, 113.
Desmotropy in phenols, 1404.
Desylacetophenone, TRANS., 643.
—— action of phenylhydrazine on, TRANS., 647.
—— oximes of, TRANS., 650.
Desylamine, 890.
Desylanisoïl, para-, TRANS., 969.
Desylphenol, para-, TRANS., 965.
fusion of, with potash, TRANS., 971.
reduction of, with hydriodic acid, TRANS., 971.
Desylphthalamic acid, 890.
Desylphthalimide, 890.

Development of frog's spawn, influence of inorganic salts on, 393.
Dextroatropine, 75.
Dextrococaine, 647, 913.
Dextroecgonine, 646, 913.
Dextrinase, 998.
Dextrins, benzoyl derivatives of, 578.
Dextrose, action of ethyl acetoacetate on, in presence of alcoholic ammonia, 732.
—— benzoyl compounds of, 578.
—— copper solution for the estimation of, 198.
—— formation of volatile fatty acids from, 731.
—— synthesis of, 466.
Dextrosecarboxylic acid phenylhydrazide, 154.
Dextrotropic acid, 74.
Diabetes, phloridzin, 1336, 1337.
Diabetic coma and acetonuria, 399.
Diacetamide, 1239.
Diacetamido-orthobromacetylthymol, para-, 602.
Diacetamidophenylhydrazine, 151.
Diacetyl, action of benzaldehyde and ammonia on, Trans., 8.
—— action of cinnamaldehyde and ammonia on, Trans., 11.
—— action of salicylaldehyde and ammonia on, Trans., 10.
—— symmetrical tetrabromo-, 359.
—— tetrachloro-, action of ammonia and ethylenediamine on, 475.
—— —— derivatives of, 232.
—— trichloramido-, 233.
Diacetylbrazilein, dibromo-, 997.
Diacetylbromotoluylenediamine, 975.
Diacetylbutane, $\omega\omega_1$-, Trans., 241.
Diacetylchloranilic acid, 1271.
Diacetylcyanhydrin, tetrachloro-, 233.
Diacetyldiamidophenylamine, 1115.
Diacetyldiamines, 1115.
Diacetyldicyanhydrin, tetrachloro-, 233.
Diacetyl-αω-diethylpentane, αω-, Trans., 29, 32.
Diacetyl-αω-diethylpentanedioxime, αω-, Trans., 33.
Diacetyldinitramidodiphenylamine, 1114.
Diacetyldiparatolyldiamidomethylene-orthophenylenediamine, 246.
Diacetyldiphenodioxazine, 491.
Diacetyldiphenylpropylamine, 1423.
Diacetylglyoxylic acid, tetrachloro-, 132.
Diacetylhydrolapachone, 1310.
Diacetylhydroisolapachone, 1310.
Diacetylmesoanthramine, 1426.
Diacetylmetaxylidine, 1315.
Diacetylorthodiamidotoluene, 1115.
Diacetylorthophenylenediamine, 1115.
Diacetyloxalenediamidoxime, 123.
Diacetylparadesylphenol, Trans., 968.
Diacetylpentane, αω-, action of dehydrating agents on, Trans., 13.
—— —— action of reducing agents on, Proc., 1889, 145.
—— —— condensation products of, Trans., 26.
Diacetylphenamidophenol, 159.
Diacetylphenylimidophenol, 490.
Diacetylquinol, monothio-, 604.
Diacetylsalicenylamidoxime, 143.
Diacetylsuccinenediamidoxime, 125.
Diadochite from Vysočany, Bohemia, 715.
Dialdehydes, action of methylhydrazine on, 24.
Dialkyl cyanothiocarbamides, 1103.
Diallyl, derivatives of, 351.
—— first oxide of a tetrahydric alcohol from, 354.
—— hexasulphide, 577.
—— oxysulphide, 577.
—— tetrabromides, 20, 223.
Diallylcarbinol, first oxide of the pentahydric alcohol from, 353.
—— pentatomic alcohol and unsaturated glycerol from, 729.
Diallylthiocarbamide, 477.
Diamidophenazine, [2 : 2′], 1114.
Diamine-compounds, metallic, 953.
Diamines, aromatic meta-, fluorescent derivatives of, 138.
—— ortho- and polyamines, formation of azines from, 178.
—— —— action of carbonyl chloride on, 975.
—— —— action of quinone on, 1445.
—— —— oxidation products of, 1444.
Diamond from Russel Co., Kentucky, 337.
—— nature of the, 1210.
Diamylamine, chloro-, 952.
Diamyloxamide, 1388.
Diamylresorcinol, dispersion and molecular refraction of, 1201, 1202.
Dianilidomethylbromacetoacetic acid, 642.
Dianilidomethyldichloracetic acid, 615.
Dianilidonaphthalene, [2 : 2′], 629.
—— para-, 911.
Dianilidonaphthaquinone, 911.
Dianilido-orthodiazothiole, 526.
Dianilidoparaxyloquinone, 606.
Dianisylbromopentalactone, 772.
Dianisylhydroxyvaleric acid, 772.
Dianisylpentalactone, 772.
Dianisylpentolic acid, 584, 771.
Dianisylpentylenic acid, 771.
Dianisyltetrylene, 584, 772.
Dianthryl, dichloro-, and its octochloride, 638.
—— hexabromo-, 638.
—— octobromide, dibromo-, 638.
—— tetrahydride, 638.

Diaptomus, colouring matter analogous to carrotene from, 640.
Diastase, characters of, 519.
—— considered as a mixture of maltase and dextrinase, 998.
—— distribution of in malted barley, Trans., 508.
—— does the aleurone-layer secrete?, Trans., 520.
—— genesis and distribution of the two varieties of, in the resting and germinating seed, Trans., 505.
—— localisation of the secretion of, in the embryo, Trans., 493.
—— of secretion, Trans., 509.
—— —— action of, on ungelatinised starch, Trans., 510.
—— of translocation, Trans., 509.
Diazine derivatives, para-, 268, 525.
Diazines, meta-, 1158.
Diazoamides, normal and mixed, Trans., 785.
Diazoamido-compounds, nitrated, 39.
Diazoamidonitrobenzene, 39.
Diazoimidonitrotoluene, 39.
Diazobenzene, 1115.
—— chloride, action of sodium thiosulphate on, 1419.
Diazobenzeneorthotolubenzylamine, 969.
Diazobenzeneparatolubenzylamine, 969.
Diazo-compounds, action of finely divided copper on, 970.
Diazodibromobenzene sulphate, 165.
Diazometanitrobenzene-methylparatoluidide, combination of, with diazoparabromobenzene - methylparatoluidide, Trans., 793.
Diazo - β - naphthalene - methylparatoluidide, combination of, with diazoparabromobenzene - methylparatoluidide, Trans., 797.
Diazoparabromobenzene - methylparatoluidide, combination of diazometanitrobenzene - methylparatoluidide with, Trans., 793.
—— combination of diazo-β-naphthalene-methylparatoluidide with, Trans., 797.
Diazo-reactions, 971.
Diazoresorcinol, 156.
Diazoresorufin, 156.
Diazo-salt-group, and a phenyl-residue, intramolecular transformation between, 1116.
Diazosulphonic acids, improvement in Sandmeyer's reaction with, 1149.
Diazotoluene, ortho-, action of sodium sulphide on, 1420.
—— para-, action of sodium sulphide on, 1420.
Diazouracil, 1241.
Diazouracilcarboxylic acid, 1240.
Dibenzallevulinic acid, 1129.
Dibenzamide, 1289.
Dibenzenylazoxime, paranitro-, 45.
Dibenzyldiazoximeoxalene, 250.
Dibenzoylacetonitrile, 1251.
Dibenzoylamidoethylpiperonylcarboxylic acid, Trans., 1059.
Dibenzoylbromotoluylenediamine, 976.
Dibenzoylcarbamide, asymmetrical, 1253.
Dibenzoylcinnamene, αβ-, Trans., 662.
—— action of bromine on, Trans., 711.
—— action of heat on, Trans., 677.
—— action of hydroxylamine on, Trans., 710.
—— action of phenylhydrazine on, Trans., 708.
—— crystallography of Trans., 715.
—— distillation of, Trans., 685.
—— nitro-, Trans., 676.
—— preparation of, Trans., 672.
Dibenzoylcinnamenimide, Trans., 692.
—— crystallography of, Trans., 718.
—— dibromide, Trans., 693.
Dibenzoylethane, 1269.
Dibenzoylmethylhydrazine, 23.
Dibenzoyl-αβ-naphthylenediamine, 370.
Dibenzoylorthophenylenediamine, 370.
Dibenzoylorthotoluylenediamine, 370.
Dibenzoylpentane, ωω-, action of dehydrating agents on, Trans., 27.
Dibenzoylsalicenylamidoxime, 143.
Dibenzoyltrimethylenephenyldiamine, 1214.
Dibenzylacetic acid, 1135.
Dibenzylalsorbite, 731.
Dibenzylcarbamide, paranitro-, 487.
Dibenzyl-derivatives, formation of, 504.
Dibenzylidenediphenyline, 166.
Dibenzylmalonic acid, 1134.
Dibenzylorthodicarboxylic acid, 1143.
Dibenzylphosphine, 767.
—— Hoffman's, identity of, with tribenzylphosphine oxide, 402.
Dibenzylphosphinic acid, 767.
Dibenzylthiocarbamide, paranitro-, 487.
Dibromhydrin, α-, constitution of, 1083.
Dibutylbenzene, tertiary, 1297.
Dibutyloctohydrophenanthroline, 138.
Dibutyric acid, γ-thio-, 1221.
Dibutyronitrile, γ-thio-, 1221.
Dicalcium phosphate, 1056.
Dicarbanilido-α-benzildioxime, 252.
Dicarbanilido-β-benzildioxime, 253.
Dicarbanilido-γ-benzildioxime, 253.
Dicarbanilidohydrazobenzene, 614.
Dicarbanilidosalicylaldoxime, 251.
Dicinnamylorthodiamidotoluene, 1115.
Dickinsonite from Branchville, 1072.
Dicoumarin, 584.
Dicresol, diamido-, action of nascent nitrous acid on, 38.

Dicyanobenzene, meta-, properties of, 147.
Dicyanobenzenylamidoxime, 1120.
Dicyanobenzyl disulphide, ortho-, 1251.
Dicyanodibenzylamine, ortho-, 1251.
Dicyano-β-naphthenylamidoxime, 1121.
Didehydrotrichlorodihydroxypiperazine, 231.
Di-diphenyltriazole, 271.
Diet, effect of, on the secretion of amidic substances, 278.
Diethoxydichloroquinols, α- and β-, 137.
Diethoxydichloroquinone, para-, 136.
Diethoxydiphenyldiketopiperazine, 1161.
Diethoxydiphenylpiperazine, nitroso-para-, 1332.
Diethoxyphenyldiketopiperazine, para-, 1333.
Diethyl β-dichloromuconate, TRANS., 934.
Diethylacetamide, 473.
Diethylacetanilide, 473.
Diethylacetic anhydride, 473.
—— chloride, 473.
Diethylacetonitrile, 474.
Diethylallylthiocarbamide, 1241.
Diethylamylcarbamide, 1241.
Diethylaniline, thio-, 611.
Diethylbenzidinephthalic acid, 1298.
Diethylbenzoylethylmethane, 493.
Diethylbenzylthiocarbamide hydrochloride, 1241.
Diethyldimethylenetrisulphone, 1093.
Diethylenediamine, 476.
Diethylethylamine, β-, 474.
Diethylethylenepseudothiocarbamide, 1242.
Diethylglutaric acid, 878.
Diethylguanidine, 1241.
Diethylmethyluracil, 31.
Diethyloxetone, 869.
Diethyloxetonecarboxylic acid, 869.
Diethylphosphorous acid, TRANS., 634.
Diethylpropylthiocarbamide picrate, 1241.
Diethylpyrroline, [1], 908.
Diethylsuccinic acids, symmetrical, 740, 13.
—— —— asymmetrical, 743.
Diethylsulphonediethylmethane, 56.
Diethylsulphonediiodomethane, 56.
Diethylsulphonedimethylmethane, 56.
Diethylsulphonemethane, 56.
Diethylsulphonethiophenylmethane, 57.
Diethylsulphonethylmethylmethane, 56.
Diethylthiocarbamide, derivatives of, 1241.
Diethyltrimethylenepseudothiocarbamide, 1212.
Diffusion, influence of, on the solvent action of liquids, 555.
Diformyldiamidophenazine, 800.
Difurfuraldiphenyline, 166.
Difurfurodiacetylene, dibromo-, 960.
Digestibility of boiled milk, 650.
— of rice-straw, 546.
— of the proteïds of various grasses, 657.
Digestion, artificial and natural, 536
—— —— of agricultural feeding stuffs, 1451.
—— —— of proteïds, 275.
—— in the pig, 183.
—— of abuminoïds, effect of "saccharin" on, 1450.
— of beef and fish, influence of cooking on, 1450.
Digitalin, 171.
—— crystallised, 65.
Digitogenin, 996.
Digitonin, composition of, 996.
Dihexolactone, 868.
Dihexonic acid, 869.
Dihexyl ketone, TRANS., 533.
—— —— hydrazone of, TRANS., 535.
—— —— oxime of, TRANS., 535.
Dihexylcarbinol, TRANS., 536.
Dihomobenzenylazoime, ortho-, 256.
—— para-, 48.
Dihydroapiole, 1294.
Dihydrodiphenyldihydroxyantetrazine, 70.
Dihydrodiphenylenehydroxyanthraquinone, 515.
Dihydroparadinitroazobenzene, 1116.
Dihydrophthalic acid, 1278.
—— —— dibromide, 1278.
—— —— dihydrobromide, 1278.
Dihydropyrroline, 65.
derivatives of, 1430.
Dihydroquinazoline, 1443.
Dihydroquinazolines, 1443.
Dihydroterephthalic acid dibromide, $\Delta^{1 \cdot 3}$-, 1131.
Dihydroxyamidonaphthalene, 2′ : 2 : 1-, 628.
Dihydroxybenzoylphosphinic acid, 619.
Dihydroxybenzylidenediphenyline, ortho-, 166.
Dihydroxydihydroquinoline, chloro-, 1128.
Dihydroxydimethylglutaric acid, 1099
Dihydroxydimethylheptamethylene, ortho-, PROC., 1889, 145.
Dihydroxydimethyltriphenylmethane, 897.
Dihydroxydinaphthylphenylmethane, 902.
Dihydroxydiphenylamine, 369.
Dihydroxydithiobenzoic acid, 163.
Dihydroxyethylbenzene, metapara-, 55.
Dihydroxylamine barium chloride, 559.
—— cadmium chloride, 559.
—— zinc chloride, 558.

Dihydroxymaleic acid, the so-called, 958.
Dihydroxynaphthalene, Trans., 633.
Dihydroxynaphthalene, [2 : 2′], 627.
Dihydroxynaphthalene, 1 : 1′ : 2 : 2′-dichloro-, 629.
Dihydroxynaphthalene, 1 : 3 : 3′ : 1′ : 2 : 2′-tetrachloro-, 629.
Dihydroxyparaquinones, para-, action of hydroxylamine hydrochloride on, 493.
Dihydroxyphenazine, 801.
Dihydroxyphosphinic acids, 618.
Dihydroxypyromellitic acid, pyrazolone derivative of, 984.
Dihydroxyquinoline, [1 : 4], 523.
Dihydroxyquinone, chloropara-, 242.
—— —— action of aniline on, 756.
—— diethyl ether, 967.
—— iodochloro-, 242.
Dihydroxythymoquinone, constitution of, 884.
Dihydroxytoluquinone, Zincke's, constitution of, 756.
Diisoamylbenzene, dispersion and molecular refraction of, 1201, 1202.
Diisobutyl dichloroglycollate, 236.
Diisopropenyl, 728.
Diketohexane, hexachlor-α-, 964.
Diketohydronaphthalene, decachloro-[2′ : 2], 629.
—— tetrachloro-, and its decomposition products, 784.
Diketohydroxyhexene, pentabromo-, 1109.
Diketones, action of methylhydrazine on, 24.
—— new class of, 388.
Diketones, α-, action of aldehydes and ammonia, on, Trans., 8.
—— α-, reduction of, Proc., **1890**, 31.
Diketopentamethylene derivatives, action of amines on, 1090.
Diketopentamethylenehydroxycarboxylic acid, chloro-, 131.
—— —— dichloro-, 132.
Dilaurylcarbinol, Trans., 983.
Dilaurylcarbinyl acetate, Trans., 984.
Dimethoxydichloroquinols, α- and β-, 137.
Dimethoxydichloroquinone, para-, 136.
Dimethoxydiphenylpiperazine, action of nitrous acid on, 1332.
Dimethoxyphenylglyoxylic acid, 967.
Dimethoxyterephthalic acid, 986.
Dimethyl berberilate, Trans., 1050.
—— dichloroglycollate, 236.
—— diethyl oxalate, 236.
—— dipropyl glycol, Proc., **1890**, 138.
—— methylaspartate, 870.
Dimethyl-ω-acetylcaproic acid, αω-, Proc., **1890**, 117.
Dimethylacetylene and its tetrabromides, 1220.
Dimethyladipic acid, symmetrical, 132.
Dimethylamidobenzene-α-azonaphthalene, 1148.
Dimethylamidodiphenylamine, dinitro-, 1410.
Dimethylamidohexylene, 1001.
Dimethylamidohydroxyquinone, 757.
Dimethylaniline, action of aluminium chloride on, 137.
—— thio-, 610.
Dimethylanilinesulphonic acid, 610.
Dimethylanthracene, dibromo-1 : 3-, 511.
Dimethylanthracylene, meta-, 511.
Dimethylanthranol, [1 : 3], 511.
Dimethylanthraquinone, [1 : 4], 512.
Dimethylapionole, 35.
Dimethylasparagine, 870.
Dimethylbenzoic acid, 3 : 5-dinitro-2 : 4-, 981.
—— —— 3-nitro-2 : 4-, 980.
Dimethyl-αα′-diacetylpentane, αα′-, Proc., **1890**, 116.
Dimethyldiethylammonium chloride and hydroxide, action of heat on, Trans., 780.
Dimethyldihydroxybenzophenone, 899.
Dimethyldimethylenetrisulphone, 1093.
Dimethyldiphenylaldine, 373.
Dimethyldiphenyldiamidomethylene-orthophenylenediamine, 246.
Dimethyldiphenylthiocarbazide, 1260.
Dimethylenediparatoluidine, 888.
Dimethylethylenediamine, 954.
Dimethyl-2-ethylquinoline-1-orthocarboxylic acid, [3 : 3′], 1327.
Dimethylglutaric acid, 878.
Dimethylglutaric acid, αα-, 1099.
Dimethylglutaric acid, symmetrical, 1099.
Dimethylglutaric acids, isomeric symmetrical, 132.
—— anhydride, αα-, 1099.
—— —— dibromo-αα-, 1099.
Dimethylheptamethylene, formation of, Proc., **1889**, 145.
Dimethylindene, metamido-βγ-, 1138.
Dimethylindigo, 383.
Dimethylisopropenylcarbinol, 727.
—— action of acids on, 728.
Dimethylketol, 1234.
Dimethylmandelic acid, orthopara-, 979.
Dimethyloxetone, 868.
Dimethyloxetonecarboxylic acid, 868.
Dimethylparamidophenyl ethylxanthate, 605.
Dimethylphenylglyoxylic acid, 5-nitro-2 : 4-, 980.
Dimethylpimelic acid, αα′-, Proc., **1890**, 117.
Dimethylpyridinecarboxylic acid, 795.
Dimethylpyridinedicarboxylic acid, 1002.

Dimethylpyrrolidine, 1000.
—— nitroso-, 1001.
Dimethylpyrroline, αβ-, molecular weight of, 906.
Dimethylquinol, dichloro-, 1247.
Dimethylquinoline, amido-, 1004.
Dimethylquinoline-α-aldehyde, ortho-para-, 1158.
Dimethylquinoxaline, tetrachloro-, 232.
Dimethylsuccinamic acid, α-dichloro-symmetrical, 958.
Dimethylsuccinic acid, asymmetrical, 742.
—— —— α-dichloro-, substitution products of, 957.
—— acids, symmetrical, relation of, to pyrocinchonic acid, 743.
—— —— the two symmetrical, 743.
—— anhydride, α-dichloro-symmetrical, 957.
—— —— —— action of phenylhydrazine on, 1327.
Dimethylstrychnine, 1448.
Dimethyltartaramide, tetrachloro-, 233.
Dimethyltartarimide, tetrachloro-, 233
Dimethyltaurine, β-, 128.
Dimethyltaurocarbamic acid, 128.
Dimethylterephthalic acid, [2 : 5], 982.
Dimethylterephthalic acid, [2 : 6], 981.
Dimethyltetramethylenediamine, αβ′-1155.
Dimethyltetraphenylethane, asymmetrical, 959.
Dimethylthiocarbamide, 477.
Dimethyluracil, 31.
Dimethylvalerolactone, 590.
Dinaphthyl bisulphide, diamido-, 994.
—— sulphide, αβ-, 1312.
—— sulphides, 1311.
—— sulphoxide, αα-, 1311.
Dinaphthylamine, αβ-, behaviour of, when combining with diazobenzene, 385.
Dinaphthylcarbamide chloride, β-, 633, 634, 993, 1311.
Di-α-naphthyldiamido-orthodiazothiole, 526.
—— cyanide, 527.
Di-β-naphthyldiamido-orthodiazothiole, 527.
—— cyanide, 527.
Di-α-naphthyldiketodihydroparadiazine, 269.
Dinaphthyl-αγ-diketopiperazine, α-1309.
Dinaphthyl-αγ-diketopiperazine, β-, 1309.
Di-β-napthylketone oxide, 510.
—— —— bromo-, 510.
—— —— dinitro-, 510.
Dinaphthylmethane, 511.
Dinaphthylpiperazine, β-, 1333.
Dinaphthylsulphone, αα-, 1312.
Dinaphthylsulphone, αβ-, 1312.
Dinaphthylsulphone, ββ-, 1311.
Dioxalparatoluidide, 525.
Dioxanilide, 525.
Dioxyberberine, Trans., 1003, 1087.
—— action of alkalis on, Trans., 1089.
—— constitution of, Trans., 1008.
Dioxymethylenephenylglyoxylic acid, 966.
Dipalmitylcarbinyl acetate, Trans., 987.
Diphenacylparatoluidine, 525.
Diphenamidophenylene, 158.
Diphenic anhydride, molecular weight of, 715.
Diphenyl, action of nitrous anhydride on, 1401.
—— conversion of aniline into, 972.
—— derivatives of, 782, 897.
—— diamidopara-, action of nascent nitrous acid on, 38.
—— $\Delta^{1\;3}$ dihydroterephthalate, 1132.
—— $\Delta^{2\;5\ \mathrm{cistrans}}$ dihydroterephthalate, 1131.
—— dithiodimethyl ether, 605.
—— orthoparadicyanide, 167.
Diphenylacetylenediureine and its derivatives, 1290.
Diphenylaldine, 373.
Diphenylamine, action of nitrous anhydride on, 1401.
—— dinitramido, 1114.
—— orthamido-, 1113.
—— orthonitro-, 1113.
—— paramido-, 609.
—— triamido-, 1114.
Diphenylamineparacarboxylic acid, metanitro-, 374.
Diphenyl-β-benzoylpropionic acid, α-, Trans., 681.
—— —— action of heat on, Trans., 685.
—— —— action of hydroxylamine on, Trans., 683.
—— —— action of phenylhydrazine on, Trans., 682.
—— —— ethylamide of, Trans., 706.
—— —— methylamide of, Trans., 703.
—— —— reduction of, Trans., 681.
Diphenylbromotoluquinoxaline, 976.
Diphenylbutane, 1408.
Diphenylbutylene, 1408.
Diphenylcarbamide, metamido-, 760.
—— metanitro- and paranitro-, 760.
Diphenylcarboxyanilide, para-, 759.
Diphenyldiamido-orthodiazothiole, 526.
Diphenyldibutine ketone, paradinitro-, 162.
Diphenyldichlorodiketoparadiazine, 526.
Diphenyl-αγ-diethyl-βδ-diketopiperazines, 1160.
Diphenyldiketodihydroparadiazine, 268.
Diphenyldiketoparadiazine, 526.

Diphenyl-αγ-diketopiperazine, 1332.
Diphenyl-αδ-diketopiperazine, 1333.
Diphenyl-αγ-diketopiperazine-βδ-homocarboxylic acid, 1162.
Diphenyl-αγ-dimethyl-βδ-diketopiperazines, isomerism of, 1160.
Diphenyldimethylpyrazoloneacetic acid, 645.
Diphenyldisazonaphtharesorcinol, 261.
Diphenylene ketone oxide, tribromo-, 893.
Diphenylenebisazodimethylaniline, 167.
Diphenylenebisazo-β-naphthol, 167.
Diphenylenebisazoresorcinol, 167.
Diphenylenemetaphenylenediamine, amido-, 614.
Diphenylethylamine, β-, 1407.
Di-phenylethyltriazole, 271.
Diphenylfurfuran, Trans., 944, 953.
—— reduction of, Trans., 955.
—— tetrabromo-, Trans., 954.
Diphenylfurfurancarboxylic acid, Trans., 951.
—— —— action of bromine on, Trans., 958.
Diphenylfurfurandicarboxylic acid, Trans., 951.
Diphenylglutaric acid, 132.
—— —— symmetrical, 384.
Diphenylhomofluorindine, 1444.
Diphenylhydrazine, derivatives of, 1259.
Diphenylhydroxykyanidine, 407.
Diphenylimidophenylene, 490.
Diphenyline, derivatives of, 166.
Diphenylizinedihydroxytartaric acid, metanitro-, 151.
Diphenylketopiperazine, 1160.
Diphenylmetadiazine, amido-, formation of, 1159.
Diphenylmetaphenylenediamine, paranitroso-, 613.
Diphenylmethane, derivatives of, 1122.
Diphenyl-αβ-naphthatriazine, Trans., 331.
Diphenylnaphthylamine, 1410.
Diphenylnaphthylamine-blue, constitution of, 1308.
Diphenyl-β-naphthylcarbamide, 633.
Diphenylnitrosoketopiperazine, 1161.
Diphenylorthoparadicarboxylic acid, 167.
Diphenylparanaphthalenediamine, 911.
Diphenyl-5-phenylpyrrolidone, 3-, Trans., 683, 696.
Diphenylphosphoryl chloride, 34.
—— thiochloride, 35.
—— trichloride, 35.
Diphenylphthaloylic acid, 897.
Diphenylpiperazine, 1332.
Diphenylpropyl alcohol, 1423.
Diphenylpropylamine, 1422.
Diphenylpropylcarbamide, 1422.
Diphenylpropyloxamide, 1422.
Diphenylpropylphenylthiocarbamide, 1422.
Diphenylpyrroylcrotolactone, 1000.
Diphenyl-β-pyrroylpropionic acid, α-, 1000.
Diphenylquinoline, αβ-, 1142.
Diphenylrosamine, 158.
Diphenylselenone, 34.
Diphenylsuccinic anhydrides, 1135.
Diphenylsulphideorthocarboxylic acid, 1292.
Diphenylsulphonebromopropane, 988.
Diphenylsulphonemethane, 56.
Diphenylsulphonethylamine, 380.
Diphenylsulphonisopropyl alcohol, symmetrical, 780.
Diphenyltetrazine, nitro-, Trans., 51
Diphenylthiocarbamide, action of allyl bromide on, Trans., 303.
—— action of benzyl chloride on, Trans., 297.
Diphenylthiocarbazinic acid, 1260.
Diphenylthiosemicarbazide, metanitro-, 151.
—— parabromorthonitro-, 152.
Diphenyltolylenedicarbamide, 760.
Diphenyltricyanocarboxylic acid, 1252.
Diphenyltrimethylene cyanide, αα′-, 384.
Diphthalylditrimethylenetriamine, 976.
Dipropionamide, 726
Dipropionylnaphthylenediamine, 1115.
Dipropionylorthodiamidotoluene, 1115.
Dipropylamido-γ-disulphide hydrochloride, 472, 1090.
Dipropylcarbamide, 176.
Dipropyldiphenyldiketodihydroparadiazinecarboxylic acid, 270.
Dipropyldisulphide-γ-diphthalamic acid, 172.
Dipropylglutaric acid, 879.
Dipropylthiocarbamide, 476.
Dipseudocumyltetrazine, Trans., 56.
Dipyrogallopropionic acid, 982.
Diquinoyltetroxime, 1403.
Diresorcinyl tetrabenzoate, 136.
Disazobenzeneparachlorophenylhydrazine, tetranitronitroso-, 1119.
Disinfectant powders, carbolic, examination of, 300.
Dispersion, anomalous, rotatory, in iron, cobalt, and nickel, 673.
—— of acids of the acetic series, 1353.
—— of alcohols of the fatty series, 1034.
—— of allylbenzene- and propenylbenzene-derivatives, 748.
—— of carbon-compounds, 1353.
—— of phosphorous oxide, Trans., 566.
Dispersive power and molecular re-

fractive energy of aromatic derivatives with saturated lateral chains, relation between, 1201.
Dispersive power of aqueous solutions, 673.
Dissociation of amine hydrochlorides and salts of the fatty acids in solution. 684.
—— of salts containing water, 206.
—— of substances in solution, 325.
—— tension, compounds which have a, equal to the vapour pressure of their saturated solution, 553.
—— theory, studies in chemical optics with reference to, 313.
Dissolution, heat of, of sulphuric acid solutions, **Trans.**, 94—114, 165—177.
Distillation, fractional, under reduced pressure, apparatus for, 329, 556.
—— of wood, products of the, 956.
Disulphones, 55.
Diterpodilactones, α- and β-, 873.
Diterpolactonic acids, α- and β-, 873.
Diterpoxylic acids, α- and β-, salts of, 873, 874.
Diterpylic acid, α-, 874.
Dithiodibutyramide, γ-, 1221.
Dithiodibutyric acid, γ-, 1221.
Dithionaphthol, αα-, 1306.
Dithioxamide, 29.
Dithymol, 1403.
Ditolubenzylthiocarbamide, ortho-, 978.
—— para-, 969.
Ditoluene, dinitroso-, 1122.
Ditoluidotoluquinone, 912.
Ditoluylene sulphoxide, para-, 1136.
Ditolyl, diamidopara-, action of nascent nitrous acid on, 38.
—— dihydrosulphide, ortho-, 606.
Ditolylcarbamide, ortho-, 1285.
Ditolyldiamido-orthodiazothiole, ortho-, and its derivatives, 527.
—— para-, 527.
—— cyanide, para-, 527.
—— nitrosopara-, 527.
Ditolyldiketodihydroparadiazine, para-, 269.
Ditolyl-αβ-diketopiperazine, para-, 1162.
Ditolyl-αγ-diketopiperazine, ortho-, 1285.
—— para-, 1284.
Ditolylethyltriazole, para-, 271.
Ditolylketoxime, para-, 1412.
Di-tolylmethyltriazole, para-, 271.
Di-tolylphenyltriazole, para-, 271.
Ditolylpiperazine, 1161.
Ditolylpiperazines, ortho- and para-, 1333.
Ditolyltetrazine, dibromopara-, **Trans.**, 51.
Ditolyltetrazine, nitroortho-, **Trans.**, 54.
—— nitropara-, **Trans.**, 51.
—— ortho-, **Trans.**, 52.
—— para-, and its derivatives, **Trans.**, 50.
Ditolyltetrazinesulphonic acid, ortho-, **Trans.**, 53.
Ditriazole derivatives, 271.
Di-trimethylenephenyltriamine, 976.
Diuretin, 1475.
—— analysis of, 1475.
Divalolactone, 867.
Divalonic acid, 868.
Dixylyldiamido-orthodiazothiole, meta-, 528.
Dixylyldiketodihydroparadiazine, para-, 269.
Dodecahydrotriphenylbenzene, 1423.
Dog, hæmoglobin of the, 273.
—— urine of the, nitrogenous constituents of, 279.
Dog-fish, formation of urea in, 1451.
Dropsy, nature of the effusion in, 1173.
Drugs, estimation of ash in, 833.
Drying apparatus for fodders containing drying oils, 671.
—— substances under diminished pressure, 1185.
Durylanilide, 759.
Dyes of the benzein-group, 157.
—— Weselsky's resorcinol, 156.
Dyslyte, 872.

E.

Earths, rare, estimation of, 565.
Ecgonine, oxidation of, 1449.
Effusions, pathological, 1173.
Egg, detection of the colouring matter of the yolk of, 840.
Egg-substance, estimation of, 840.
Egg-yolk, heat of combustion of, 938.
Egyptian blue, 215.
Eikosihydrotriphenylbenzene, 1423.
Elaidic acid, addition of chlorine and halogen acids to, 1396.
Electric arc, action of, on gases, and its employment for demonstrations, 1047.
—— discharge, prolonged action of, on iodine, 687.
Electrical conductivity as a means of investigating the interaction of acids of complex function, 204.
—— —— change of, in freshly-prepared solutions, 204.
—— —— of air due to the formation of ozone, 676.
—— —— of aspartic acid, 204.
—— —— of distilled water, 1357.
—— —— of fused and solid salts, 1037.

Electrical conductivity of hydrogen chloride in different solvents, 97.
—— —— of phenols and hydroxybenzoic acids, 677.
—— —— of solid mercury, 98.
—— —— of solutions of boric acid containing mannitol, 1357.
—— —— of solutions of cadmium salts, 1203.
—— —— of some solutions at temperatures between 18° and 100°, 676.
—— —— of substituted succinic and glutaric acids, 1038.
—— —— of sulphuric acid solutions, Trans., 86—88, 158—160.
—— —— of the ammonium and aniline salts of the hydroxybenzoic acids, 1039.
—— current, oxidation of sulphides by, 1342.
—— discharge, silent, effects of the, 1358.
—— properties of semi-permeable walls, 1354.
—— resistance of gases, influence of a magnetic field on, 1359.
—— —— of iron and its alloys at high temperatures, 549.
—— —— of nitrogen peroxide, variations in the, with rise of temperature, 203.
—— —— of the alloys of ferromanganese and copper, 1356.
Electricity, development of, in electrolytes, 677.
—— passage of, through hot gases, 1037.
Electrochemical effects on magnetising iron, 678.
Electrochemistry of some organic acids, 99.
Electrodes, platinum, maximum polarisation of, in sulphuric acid, 316, 675.
—— —— polarisation of, in dilute sulphuric acid, 551, 676.
—— polarisation of, 933.
Electrolysis of a mixture of two salts in aqueous solution, 678.
—— of aluminium fluoride in igneous fusion, 1040.
—— of fatty acids, 1236.
—— of fused aluminium oxide and fluoride, 552.
—— of hydrogen carbonates, 1204.
—— of mixed solutions, 317.
—— of potassium ethyl malonate and ethyl potassium succinate, 583.
—— of silver chloride dissolved in sodium thiosulphate, 1204.
—— with semi-permeable walls, 1354.
Electrolytes, binary, difference of potential between two dilute solutions of, 1355.
Electrolytes, conditions of equilibrium between, 437.
—— development of heat and electricity in, 677.
—— different, surface tension of polarised mercury in, 552.
Electrolytic cells, resistance of, 317.
—— estimations and separations, use of double pyrophosphates in, 294.
—— separations, 294, 664. 1028, 1029.
Electrometer, Lippmann's capillary, limits of accuracy of, 552.
Electromotive force of metallic salts, 843.
—— —— seat of the variation of, with temperature, 1035.
—— forces, changes in, produced by changes of concentration of the exciting liquid, 1035.
—— —— of cells containing mixed salt solutions, 202.
Element, new, evidence of a, in tellurium, antimony, and copper, 434.
Elements, atomic refraction of, 313.
—— relation between the atomic volume of, and the influence of, on steel, 567.
—— structure of the line spectra of, 674.
Eleonorite, 219.
Embryo and endosperm, relation of, Trans., 474.
—— form in which reserve starch enters, Trans., 513.
—— localisation of the secretion of diastase in the, Trans., 493.
—— visible changes in, during germination, Trans., 466.
—— young, secretion of an amylohydrolyst (diastase) by, Trans., 489.
Embryos, excised, development of, on foreign endosperms, Trans., 478.
—— —— of barley, culture of, on nutrient solutions, Trans., 483.
culture of, on water, Trans., 482.
Emetine, assay of, in ipecacuanha wine, 310, 548.
Endosperm and embryo, relation of, Trans., 474.
—— function of the starch of, Trans., 478.
—— visible changes in, during germination, Trans., 466.
Endosperms, foreign, development of excised embryos on, Trans., 478.
Endothermic reactions, spontaneous, and Berthelot's law of maximum work, 681.
Ensilage, experiments on, at Woburn, 286.
Enstatite, 19.

Enzymes, Trans., 835.
—— hydrolytic, origin of the, of germinated grain, Trans., 511.
Epidote as a rock-forming mineral, 460.
—— from Syphnos, 344.
Equilibrium between hydrogen, chlorine, and oxygen, 8.
—— chemical, between hydrogen chloride and hydrogen in conjunction with metals, 685.
—— in homogeneous solutions when unequally heated, 444.
Equivalents, optical, 433.
Erythrane, constitution of, 730.
Erythrene, constitution of, 730.
Erythrol, action of, on alkali alkyloxides, 935.
—— bromide, 730.
—— derivatives of, 730.
—— heat of formation of the sodium derivatives of, 935.
—— heats of combustion and formation of, 1360.
Essential oils, Maumene's test for, 834.
Etard's reaction, 978.
Ethane derivatives, stereochemistry of, 1083.
Ethanediquinolyline, 1007.
Ethenylanilidoxime, 43.
Ethenylbromotoluyleneamidine, 976.
Ethenyldiphenylamidine, 371.
Ethenyldiphenylsulphone phenyl sulphide, 988.
Ethenylditolylamidine, 371.
Ethenylethylorthophenylenediamine, 612.
Ether, action of light on, Trans., 574.
—— action of ozone on, Trans., 584.
—— conditions under which hydrogen peroxide is formed from, Trans., 574, 988, Proc., 1889, 134.
—— slow combustion of, Trans., 585.
—— vinyl alcohol a constant constituent of, 118.
Ethereal oils, 1314.
—— —— iodine absorption of, 199.
—— —— reactions of, 199.
—— salts, decomposition of, in the alimentary canal, 1013.
—— —— production of, by fermentation, 1454.
Etherification by uranium salts, 727.
Ethers, dispersion of, 1353.
Ethoxyacrylic acid from α-dichloropropionic acid, 957.
Ethoxybenzamide, 975.
Ethoxybenzyleneanthrone, 1425.
Ethoxycaffeïne, 1166.
Ethoxyhydrocotarnine methiodide, 531.
Ethoxypiaselenole, 161.
Ethoxy-α-stilbazole, 1439.
Ethyl acetate, amido-, 1268.
—— acetanilidoacetate, 1415.
—— α-acetanilidopropionate, 1416.
—— acetoacetate, action of alcohols on, 1096.
—— —— action of, on cinnamaldehyde, 768.
—— —— action of, on dextrose in presence of alcoholic ammonia, 732
—— —— condensation of carbamide with, 1249.
—— —— derivatives of, 27.
—— —— haloid derivatives of, 1238.
—— acetoneoxalate, conversion of, into symmetrical hydroxytoluic acid, 364.
—— acetylmalonate, action of, on benzamidine, 496.
—— acrylate, conversion of, into β-alanine, 862.
—— adipate, synthesis of, from ethyl potassium succinate, 583.
—— alcohol, nitro-, 857.
—— amidothiazylacetate, 1258.
—— β-amyloxyquartenylate, 865.
—— anilomethyloxalacetate, 379.
—— aniloxalacetate, 378.
—— anilpyrroylpyruvate, 1243.
—— anisenylamidoximecarboxylate, 145.
—— benzenylamidoximeoxalate, 258.
—— benzenylazoximemethenylcarboxylate, 259.
—— benzoate, amido-, salts of, 1267.
—— benzylbutenyltricarboxylate, 774.
—— benzylethenyltricarboxylate, 774.
—— benzylisobutenyltricarboxylate, 774.
—— benzylpropenyltricarboxylate, 774.
—— bromanilidodinitrophenylmalonate, 982.
—— α-bromisobutyrate, action of, on ethyl propylmalonate and isopropylmalonate, 1103.
—— bromisovalerate, action of trimethylamine on, 956.
—— α-bromobutyrate, action of triethylamine on, 234.
—— bromodinitrophenylacetoacetate, 772.
—— bromodinitrophenylmalonate, 377.
—— α-bromopropionate, preparation of, 234.
—— bromotrinitrophenylmalonate, 497.
—— bromundecylenate, 1237.
—— butenyltricarboxylate, 743.
—— butyrate, production of, by fermentation, 1455.
—— α-butyrobutyrate, 235.
—— camphoroxalate phenylhydrazone, Trans., 655.
—— camphorylmalonate, 1150.

Ethyl carbamate in the alcoholic extract of normal urine, 654.
—— chloranilate, 136.
—— chloride, nitro-, 858.
—— chlorobutenyltricarboxylate, 1101.
—— chloroformate, chlorine substitution products of, 1095.
—— chloropropenyltricarboxylate, 1101.
—— chloroxalate, 236.
—— cyanacetate and benzaldehyde, condensation products of, 1270.
—— cyanate, molecular weight of, 725.
—— cyanodiphenylsuccinate, 504.
—— cyanurate, molecular weight of, 725.
—— $\alpha\beta$-diacetopropionate, 863.
—— diacetoxysuccinosuccinate, 986.
—— diacetoxyterephthalate, 986.
—— $\alpha\alpha_1$-diacetyladipate, Trans., 204, 215.
—— —— action of phenylhydrazine on, Trans., 221.
—— —— decomposition of, by heat, Trans., 224.
—— $\alpha\omega$-diacetyl-$\alpha\omega$-diethylpimelate, Trans., 30.
—— $\alpha\omega$-diacetylvalerate, Trans., 228.
—— —— hydrolysis of, Trans., 229.
—— diallyldicarboxyglutarate, 879.
—— dibenzoyloxypyromellitate, 985.
—— α-dibenzoyloxysuccinosuccinate, 986.
—— dibenzoyloxyterephthalate, 986.
—— dibenzoylsuccinate, preparation of, Trans., 949.
—— dibenzyldicarboxyglutarate, 879.
—— dibenzyloxyterephthalate, 986.
—— dibromadipate, Trans., 372.
—— dibromodinitrophenylmalonate, 982.
—— dicarbanilidodibromohydroquinonedicarboxylate, 500.
—— dicarbanilidodichlorohydroquinonedicarboxylate, 499.
—— dichloradipate, Trans., 939.
—— dichloropyromucate, 600.
—— β-dichloropyromuconate, Trans., 933.
—— dicyanacetate, 1395.
—— diethyldicarboxyglutarate, 878.
—— dihydrodiamidopyromellitate, 983.
—— dihydrodibenzoyloxypyromellitate, 986.
—— dihydrodibenzoyloxyterephthalate, 987.
—— α-dihydrodibenzyloxyterephthalate, 986.
—— dihydrogen hydrocamphorylmalonate, 1151.
—— dihydroxyterephthalate, 986.
—— diimidodiethyladipate, Trans., 218.
—— dimethoxyterephthalate, 986.
Ethyl $\alpha\alpha'$-dimethyl-$\alpha\alpha'$-diacetylpimelate, Proc., 1890, 117.
—— dimethyldicarboxyglutarate, 878.
—— dimethyldicyanoglutarate, 132.
—— dimethylpimelate, Proc., 1890, 117.
—— 2 : 5-dimethylpyrrolinecarboxylate, formation of, 1155.
—— dinitrophenylacetoacetate, 1418.
—— diphenacylacetoacetate, 258.
—— diphenylhydrazinediacetyladipate, Trans., 221.
—— dipropyldicarboxyglutarate, 878.
—— disodiodiacetyladipate, Trans., 216.
—— disodiotartrate, 595.
—— ethenyltricarboxylate, 742.
—— —— physical constants of alkyl derivatives of, 745.
—— ether. See Ether.
—— ethylbutenyltricarboxylate, 744.
—— ethylethenyltricarboxylate, 743.
—— ethylimidoethylphenylthiocarbamate, 1291.
—— ethylisobutenyltricarboxylate, 744.
—— ethylpropenyltricarboxylate, 743.
—— fluorides, hydrates of, 1386.
—— formanilidoacetate, 1415.
—— fumarate, action of methylamine on. 869.
—— α-heptoheptoate, 235.
—— homobenzenylamidoximecarboxylate (para-), 48.
—— hydrocamphorylmalonate, 1151.
—— hydrochloranilate, 1271.
—— hydrogen oximidosuccinates, isomerism of, 350.
—— hydroxyphenyldiphenylpyrrolinecarboxylate (ortho-), 264.
—— hydroxytetrate, 739.
—— imidoethylphenylthiocarbamate, 1291.
—— imidophenylthiocarbamate, 1291.
—— iodacetoacetate, 28.
—— iodide and triethylamine, effect of various solvents on the velocity of reaction between, 1366.
—— α-isoamyl-β-amidocrotonate, 1097.
—— isoamylmalonate, 1099.
—— isobutenyltricarboxylate, 743.
—— β-isobutoxyquartenylate, 865.
—— α-isobutyl-β-amidocrotonate, 1097.
—— isobutylparaconate, 874.
—— isohexenyltricarboxylate, 744.
—— isomuconate, Trans., 374.
—— isopropylmalonate, action of ethyl α-bromisobutyrate on, 1103.
—— lactate, production of, by fermentation, 1455.
—— maleate, action of methylamine on, 869.
—— malonate, preparation of mono-,

di-, and tri-substituted succinic acids from, 742.
Ethyl mercaptan, action of phenylthiocarbimide on, 500.
—— β-methoxyquartenylate, 865
—— α-methyl-β-amidocrotonate, 1097.
—— methylbutenyltricarboxylate, 743.
—— methylenemalonate and its isomeride, 364.
—— methylethenyltricarboxylate, 742.
—— methylisobutenyltricarboxylate, 744.
—— methyloxalacetate, action of aniline on, 378.
—— methylthiazylacetate, 1238.
—— α-naphthenylamidoximecarboxylate, 63.
—— β-naphthenylamidoximecarboxylate, 62.
—— α- and β-naphthyldiphenylpyrrolinecarboxylates, 263.
—— nitracetoacetate (?), 28.
—— nitrite, estimation of, in spirit of nitrous ether, 927.
—— nitrobenzenylamidoximecarboxylate (para-), 45.
—— nitrobenzylcarbamate (para-), 487.
—— orthoformate, 582.
—— oxalacetate, action of aniline on, 378.
—— —— action of bromine on, 133.
—— oxalenediuramidoxime dicarbonate, 124.
—— phenacylisoamylmalonate, 1100.
—— phenylacetylhexamethylenecarboxylate, Trans., 319.
—— phenylallenylamidoximecarboxylate, 42.
—— phenylbromacetate, 1135.
—— phenylcarboxysuccinate, 1135.
—— phenylenedi-diphenylpyrrolinecarboxylate (para-), 264.
—— phenylhexamethylenedicarboxylate, Trans., 315.
—— phenylhydroxyacetate, 1135.
—— phenylmethylhydroxypyrimidineacetate, 69.
—— phenylmethylhydroxypyrimidinepropionate, 70.
—— phenylparaconate, 894.
—— α-phenylsulphonebutyrate, preparation of, 781.
—— phosphite, 858.
—— γ-phthalimidopropylmalonate, 1129.
—— potassium malonate, electrolysis of, 583.
—— —— succinate, electrolysis of, 583.
—— propenyltricarboxylate, 742.
—— —— synthesis of mesaconic and citraconic acids from, 1101.
—— α-propiobutyrate, 235.
—— β-propoxyquartenylate, 865.
Ethyl propylmalonate, action of ethyl α-bromisobutyrate on, 1103.
—— propylparaconate, 872.
—— pyromucate, chloro-derivatives of, 452
—— pyrroylisonitrosopropionate, anhydride of, 1156.
—— pyrroylpyruvate, 1000, 1156.
—— pyrrylphenylpyrazolecarboxylate, 1244.
—— quinolineparamethenylamidoximecarboxylate, 175.
—— salicenylamidoximecarboxylate, 146.
—— sodacetoacetate, action of picric chloride on, 1418.
—— sodiophenylsulphonacetate, displacement of the sodium of, by alkyls, 781, 1137.
—— sodiotartrate, 595.
—— succinate, synthesis of, from ethyl potassium malonate, 583.
—— succinosuccinate and allied compounds, alleged tautomerism of, 983.
—— tartrate, action of alkali ethoxides on, 595.
—— terpenylate, 873.
—— tetracarbanilidotetrahydroxyterephthalate, 500.
—— tetramethylenetetracarboxylate, 879.
—— thioacetate, 582.
—— thioacetoacetate, action of phenylhydrazine on, 796.
—— —— formation of, 28.
—— tolyldiphenylpyrrolinecarboxylate (ortho- and para-), 263.
—— tricarbanilidophloroglucinoltricarboxylate, 500.
—— trichloropyromucate, 601.
—— trinitrophenylacetoacetate, 1418.
—— trinitrophenylenedimalonate, 498.
—— undecylenate, 1237.
—— valerovalerate, 235.
—— xylenylamidoximecarboxylate, 50.
—— xylylchloromalonate (meta-), 499.
—— xylyldiphenylpyrrolinecarboxylate (meta-), 263.
—— xylylmalonamate (meta-), 498.
—— xylylmalonate (meta-), 498.
—— xylylmalonmethylamate (meta-), 498.
Ethylacetanilide, 758.
Ethylallylthiocarbamide, 477.
Ethylamidoethylpiperonylcarboxylic anhydride, Trans., 1035.
Ethylaniline, 758.
—— orthonitro-, 611.
—— orthonitronitroso-, 612.
Ethylazimidobenzene, 612.
Ethylbenzamide, 43.
—— β-chlor-, 1267.

Ethylbenzamide, para-, 975.
Ethylbenzene, action of chromyl chloride on, 978.
—— action of ethylmalonic chloride on, 493.
—— derivatives of, 134.
—— isomeric derivatives of, 54.
Ethylbenzenemetasulphonic acid, 54.
—— —— orthobrom-, 55.
—— —— parabrom-, 55.
Ethylbenzeneparasulphonic acid, 54.
Ethylbenzoyldextroecgonine, 913.
Ethylbenzoylenecarbamide, 1254.
Ethylbenzylanilinesulphonic acid, sodium salt of, 611.
Ethylbromopiperonylcarboxylic anhydride, ω-amido-, Trans., 1017.
Ethylcoumarin, 777.
—— thio-α-, 624.
Ethylcoumaroxime, α-, 624.
—— acetate, α-, 624.
Ethylcoumarphenylhydrazide, α-, 624.
Ethylcrotonic acid, β-thio-, 361.
Ethyldextrococaïne aurochloride, 913.
Ethyldiacetylpyrroline, tertiary, 1430.
Ethyldibromomaleïmide, 907.
Ethyldimethylsuccinic acid, 743.
Ethylene bromide, action of ammonia on, 952.
—— glycol, oxidation of, in alkaline solution with lead peroxide, 20.
—— imidophenylthiocarbamate, 1292.
—— selenide, 950.
—— tetraphenyl hexacyanide, 1253.
Ethylenediaminedibromopraseocobalt salts, 953.
Ethylenediaminedichloropraseocobalt salts, 953.
Ethylenediaminedichlorovioleocobalt salts, 953.
Ethylenedi-α-naphthyldiamine, action of chloracetic and oxalic acids on, 1162.
Ethylenedi-β-naphthyldiamine, 1333.
Ethylenediparaethoxydiphenyldiamine, 1332.
Ethylenediphenyldiaminesuccinic acid and aniline, reaction of, 1164.
Ethylenelactic acid, 128.
—— —— from flesh extract, 235.
Ethyleneorthoditolyldiamine, action of chloracetic acid and oxalic acid on, 1161.
Ethyleneparaditolyldiamine, action of chloracetic and oxalic acids on, 1162.
Ethylenephenylhydrazine, 250.
Ethylenephenylhydrazinedisuccinic acid, 250.
Ethylene-ψ-selenocarbamide, 880.
Ethylenetetraphenyldithiosemithiocarbazide, 251.
Ethylenetriphenylthiosemicarbazide, 251.
Ethylformanilide, 758.
Ethylglycolylamidocumic acid, meta-, 270.
Ethylglycolylparatoluidide, 269.
Ethylglycolylparaxylidide, 269.
Ethylhydrasteïne, 533.
Ethylhydrastine, 74, 649.
—— ethiodide, 533.
—— hydroxide, 1169.
Ethylhydroberberine, 1012.
Ethylhydroxyxanthine, 32.
Ethylidene trichlorolactate, tetrachlor-, 27.
Ethylideneanisenylamidoxime, 145.
Ethylidenebenzenylamidoxime, 44.
Ethylidenebromophenylsulphone, 381.
Ethylidenechloroparatolylsulphone, 380.
Ethylidenechlorophenylsulphone, 379.
Ethylidenediethylsulphone, 55.
—— chloride, 55.
Ethylidenemetanitrophenylhydrazine, 150.
Ethylidene-β-naphthenylamidoxime, 62.
Ethylideneparahomobenzenylamidoxime, 48.
Ethylideneparanitrobenzenylamidoxime, 46.
Ethylidenepropionic acid, 585.
Ethylisobarbituric acid, 32.
Ethylisocrotonic acid, β-thio-, 361.
Ethylisophthalic acid, 1283.
Ethylitamalic acid, salts of, 588.
Ethylmalonic chloride, action of, on ethylbenzene, 493.
Ethylmercaptomethylthiazoline, 860.
Ethylmethyldihydropentene methyl ketone, Trans., 251.
Ethylmethylhexamethylene, α-iodo-, Trans., 23.
Ethylmethylnitrouracil, 32.
Ethyl-2-methylpyrrolidone-2-carbothioxylamide, [1], 793.
Ethyl-2-methylpyrrolidone-2-carboxylamide, [1], 793.
Ethyl-2-methylpyrrolidone-2-carboxylic acid, [1], 793.
Ethyl-3′-methylquinoline-1-carboxylic acid, [2′], 1326.
Ethylmethylsuccinic acid, symmetrical, 743.
Ethylmethyluracil, 31.
Ethylnaphthalenecarboxylamide, -, 158.
Ethylnaphthylamine, β-nitroso-α-, 631.
Ethyl-β-naphthylhydrazine, 61.
Ethylnitroüracil, 32.
Ethylorthophenylenediamines, 612.
Ethylorthotolylsemithiocarbazide, Trans., 262.
Ethyldibromomaleïmide, 907.
Ethylparaconic acid, 587.
Ethylparanitrobenzenyloxime nitrite, 46.
Ethylphenol, ortho-, 134.

Ethylphenol, para-, 54.

Ethylphenolmetasulphonic acid, derivatives of, 55.

Ethylphenyl propyl ketone, 493.

Ethylphenylnaphthaleneazammonium iodide, 787.

Ethylpiperonylcarboxylic acid, ω-amido-, action of heat on, Trans., 1058.

—— —— —— action of methyl iodide on, Trans., 1059

—— —— —— action of nitrous acid on, Trans., 1060.

—— —— —— preparation of, Trans., 1053.

—— —— —— salts of, with acids, Trans., 1056.

—— —— ω-chlor-, Trans., 1029.

—— anhydride, ω-amido-, Trans., 993, 1013.

—— —— —— fusion of, with potash, Trans., 1015.

opianate of, Trans., 1082.

—— ————pseudopianate of, Trans., 1076, 1080.

—— —— nitrosoamido-, Trans., 1018.

Ethylpropargylamine, 230.

Ethylpropylene, β-thio-, 361.

Ethylpyridinedicarboxylic acid, 795.

Ethylpyrroline, [1-], 907.

Ethylpyrrolines, 65.

Ethylquinol, thio-, 604.

Ethylquinoline-3 : 4′-dicarboxylic acid, 1325.

Ethylrosinduline, 908.

Ethylsuccinic acid, 742.

Ethylsulphoncyanamide, 502.

Ethylsulphonic acid, preparation of, 748.

Ethylthiocarbamideallyl cyanide, 1101.

Ethylthiocarbamidebenzyl cyanide, 1104.

Ethylthiocarbamideethyl cyanide, 1101.

Ethylthiocarbamidepropyl cyanide, 1104.

Ethylthio-β-dinaphthylamine, 1307.

Ethyltrimethyltetrahydroquinoline, 1327

Ethyltriphenylbromopyrrolone, crystallography of, Trans., 736.

Ethyltriphenylpyrrolone, Trans., 704.

—— action of bromine on, Trans., 705.

—— crystallography of, Trans., 730

Ethylxylenes and their derivatives, 882.

Ethylxylenol, 883.

Eucalyn, identity of, with melibiose, 227.

Eucalyptus honey, 122.

Eugenol, 966.

—— ethyl ether tribromide, 639.

—— presence of, in sassafras oil, 1111.

Eukairite from Argentine, 948.

Eulyte, 872.

Eurhodine, constitution of, 1265.

Eurhodines, formulæ of, 1444.

Euxanthic acid, constitution and properties of, 505.

Euxanthone, properties of, 506.

—— synthesis of, 506.

Euxanthone-group, 504.

Euxanthone-series, compounds of, 389.

Evaporation by aid of heat applied from above, 5.

Expansion by heat of sulphuric acid solutions, Trans., 114—121, 177—184.

Extraction apparatus, 663.

F.

Fabrics, dyed, estimation of indigo in, 931.

Fairfieldite from Branchville, 1072.

Fat, absorption of, 1171.

—— absorption of, in the intestine, 183.

—— estimation of, in milk, 837.

—— estimation of, in milk in dairies, 1346.

—— estimation of, in poppy cake, 306.

—— estimation of, in sour milk, 304

——extraction apparatus, simplified, 301.

—— extraction of, from milk solids 91

—— in milk, volumetric estimation of, 92.

—— of bone marrow, 652.

—— rapid estimation of, in milk, 304.

Fats, analysis of, 91, 929.

—— detection of cotton-seed oil in, 930.

—— different, absorption of, by the alimentary canal, 811.

—— estimation of, in feeding stuffs, 930.

—— examination of, 1347, Proc., 1890, 72, 91.

—— ferments which decompose the, in plants, 1155.

—— melting and solidifying points of, 929.

—— neutral, estimation of, 200

—— of fodder, composition of, 657.

—— optical examination of, 91.

Fayalite, artificial, 20.

Feeding stuffs, agricultural, artificial digestion of, 1451.

Felspars, barytic, from Sweden, 343.

Fergusonite, from Llano Co., Texas, 459.

Ferment, diastatic, of ungerminated wheat, 650

—— —— of the liver, 185.

—— inverting, in koji, 281.

—— which destroys sugar, presence in chyle of a, 810.

Ferment-action of bacteria, 916.

Fermentation, acetic, action of light on, 1181.

—— alcoholic, formation of hydrogen sulphide during, 1454.

Fermentation of invert sugar, 950.
—— aldehyde as the chief product of a, 1180.
—— ammoniacal, of uric acid, 1399.
—— by the fungus of the lily of the valley, 1179.
—— influence of carbonic anhydride on the products of, 281.
—— marsh gas, 855.
—— mucous, 76.
—— of cranberry juice, 1455.
—— of glycerol and mannitol, 915.
—— of manure in absence of oxygen, 282.
—— of nitrogenous matters, loss of nitrogen in, 1340.
—— of raffinose by beer yeast, 22.
—— of sugar, formation of paralactic acid during, 78.
—— production of ethereal salts during, 1454.
Ferments, anaërobic, decomposition of albumin by, 78.
—— —— decomposition of gelatin by, 543.
—— fat-decomposing, in plants, 1455,
—— hydrolytic, terminology of, TRANS., 528.
—— unorganised, TRANS., 835.
Ferric antimonate, 216.
—— carbonylferrocyanide, 117.
—— chloride, reduction of, by boiling, 111.
—— hydroxide, action of, on aluminic and ferric salts, 946.
—— —— colloidal, molecular weight of, 1216.
—— oxide, influence of, on the decomposition of potassium chlorate, TRANS., 278.
—— —— precipitation of, by ammonia, 420.
—— oxychloride, crystallised, 1063.
—— phosphate, tetrahydrated, formation of, 292.
—— potassium arsenate, 1378.
—— pyroarsenate, 1378.
—— sodium arsenate, 1378.
—— thiosulphate, 330.
Ferricyanides, volumetric estimation of, 834
Ferro-aluminium, analysis of, 1471.
Ferrocyanide, estimation of, in gas-lime, 87.
Ferrocyanides, estimation of, in the bye-products of gas works, 834.
Ferromanganese and copper, electrical resistance of alloys of, 1356.
Ferronatrite, 455.
Ferrostibian from Örebrö, 1075.
Ferrous sodium thiosulphate, 12.
—— thiosulphate, 12.
Fertility, decrease of, by growth of tobacco, 1340.
Fibrin, blood and vegetable, heat of combustion of, 938.
—— heat of combustion of, 938.
Fibrin-ferment, action of, 1175.
Fibroferrite, 456.
Fibroin, heat of combustion of, 938.
Fichtelite, constitution of, 385.
—— properties of, 384.
Filicic acid, constitution of, 162.
Fillowite from Branchville, 1072.
Films of vaporised metal, 692.
Filter holder for drying and weighing, 193.
Fish, dog-, formation of urea in, 1451.
—— influence of cooking on the digestion of, 1450.
Fishes, gases in the swimming bladder of, 183.
Flame, production of ozone by, PROC., 1890, 26.
—— violet, produced by common salt in a coal fire, 1202.
"Flaveanwasserstoff," 351.
Flax, constituents of, TRANS., 196.
Flax-fibres, discrimination of jute-fibres from, 928.
Flesh, heat of combustion of, 938.
Flue deposits, manganiferous, estimation of zinc in, 394.
Fluid crystals, 106.
Fluorescences, new, 435.
Fluorides, heat of neutralisation of, 1.
Fluorindine, 1444.
Fluorine, action of, on different forms of carbon, 557.
—— colour and spectrum of, 329.
—— density of, 208.
Fluoroform, 724.
Fluorspar from St. Lawrence Co., New York, 337.
Fodder, &c., estimation of starch in, 1197.
—— composition of the fats of, 657.
—— sweet, production of so-called, 82.
Fodders, acid and compressed, analysis of, 1177.
—— acid, loss of nitrogen in, 1339.
—— action of dilute hydrochloric acid and of pepsin on the digestible albumin of, 651.
—— containing drying oils, apparatus for drying, 670.
Food, estimation of ash in, 833.
Foods, detection of benzoic acid in, 1031.
—— estimation of chromium and barium in, 195.
Forces, molecular, sphere of action of, 105.

Formaldehyde, 1092.
—— action of hydrogen sulphide on, 477.
—— cryoscopic behaviour of sugars synthesised from, 465.
—— preparation and properties of, 954.
—— sodium hydrogen sulphite, 1092.
Formanilide, alkylation of, 1258.
—— pariodo-, 1415.
Formanilidoacetic acid, 1415.
Formanilidopropionic acid, 1415.
Formic acid, electrochemistry and thermochemistry of, 99.
Formopariodoanilide, 1258.
Formose, molecular weight of, 466.
Formulæ, space-, 719.
Formyldeoxybenzoin, 359.
Formyldiethyl ketone, 357.
Formylethyl phenyl ketone, 358
Formylpropyl phenyl ketone, 358
Francein from 1 : 2 : 4-trichlorobenzene, 51.
Franceins, new data relating to, 51.
Frangulin, TRANS., 38.
—— hydrolysis of, TRANS., 45.
—— preparation of, TRANS., 41.
Free surface of liquids, increase of chemical energy at, 328.
Freezing of colloidal solutions, 685.
—— point of a solvent, lowering of, 846.
—— —— of isomorphous mixtures, 1209.
—— points of solutions, law of, PROC., 1890, 9.
—— —— of sulphuric acid solutions, TRANS., 331.
Fructosecarboxylic acid, 599.
Fucose, an isomeride of rhamnose, 1393.
Fucus, sugar from, 1105.
Fucus vesiculosus, gases contained in the bladders of, 916.
—— —— iodine in, 402.
Fucusaldehyde, identity of, with furfuraldehyde, 1242.
Fucusol, 33, 238, 1105.
Fumaric acid, conversion of maleic acid into, 1397.
—— —— synthesis of, 594.
—— and maleic acids, isomerism of, 368.
—— diparatoluidide, 1163.
Fumarine, 272.
Fungus of the lily of the valley, alcoholic fermentation and conversion of alcohol into aldehyde by, 1179.
Fungus-symbiosis of the Leguminosæ, 1020.
Furfuracrylamide, 960.
Furfuracrylic acid, bromo-, 960.
—— —— derivatives of, 959.
Furfuraldehyde, 1242.
Furfuraldehyde, estimation of, 1352.
—— presence of, in commercial alcohols, 1400.
Furfuraldehydediphenylhydrazone, 1260.
Furfuraldoxime, two stereochemically isomeric derivatives of, 1266.
Furfuran, trichlorobromo-, 601.
Furfuran-derivatives and sugars, relation between, 33.
Furfuran-group, 1242.
Furfurobromacrylic acid, bromo-, 960.
Furfurobromethylene, bromo-, 960.
Furfurodibromopropionic acid, bromo-, 960.
Furfur-β-phenylpropyl alcohol, γ-, 1408.
Furfur β-phenylpropylamine, γ-, 1407.
Furfur-β-phenylpropylcarbamide, γ-, 1407.
Furfurphenylethylamine, β-, 1407.
Furildoximes, α- and β-, 1245.
Furilphenylhydrazone, 1245.
Furilphenylosazone, 1245.
Furoinoxime, 1245.
Furoinphenylhydrazine, 1245.
Furotolidine, 1299.
Fusel oil, American, 859.

G.

Gadolinite from Texas, 457, 458.
Galactan, α-, 284.
Galactonic acid, lactone of, 598.
—— —— phenylhydrazide, 154.
Galactose and cerebrose, identity of, TRANS., 57.
—— identity of brain sugar with, 121, TRANS., 57.
Galactosecarboxylic lactone, 599.
Galactosediphenylhydrazone, 1260.
Galaheptose, 599.
Gallic acid, oxidation of, 1130.
—— —— phenylhydrazide, 155.
—— —— reaction of, 1275.
Gallium oxide, action of magnesium on, 694.
Gamoose, milk of the, TRANS., 754.
Garnet from the South African diamond fields, 1076.
Galvanic cell, dichromate, 1354.
—— polarisation, theory of, 314.
Gas apparatus, removal of exhausted solutions from, 557.
—— balance, 823.
—— densities, new method of determining, 321.
—— heat of solution of a, 816.
—— sampling and testing apparatus, 411.

Gas-battery, new form of, 842.
Gas-burners, new, 106.
Gases, absorption of, by mixtures of alcohol and water, 103.
—— action of the electric arc on, and its employment for demonstrations, 1047.
—— apparatus for preparing, 556.
—— automatic apparatus for the evolution of, from liquids, 6.
—— bottle for washing and absorbing, 288.
—— contained in the bladders of *Fucus vesiculosus* and *Ozothellia nodosa*, 916.
—— evolved in the putrefaction of serum albumin, 78.
—— hot, passage of electricity through, 1037.
—— hydrates of, 1386.
—— in the swimming bladder of fishes, 183.
—— influence of a magnetic field on the electrical resistance of, 1359.
—— influence of acids on the evolution of, by plants, 190.
—— refractive indices of, 201.
—— simple and rapid preparation of, 849.
—— spectra of, at low temperatures, 313.
—— titration of small quantities of, in mixtures, 290.
Gas-generator, self regulating, 847.
Gas-lime, estimation of ferrocyanide in, 87.
Gas-liquor, estimation of pyridine bases in, 1349.
Gas-volumeter, 600.
Gas-waste, &c., estimation of ferrocyanides in, 831.
Geddic acid, Trans., 59.
Gedrite from Fiskernäs, Greenland, 19.
Gelatin, decomposition of, by anaerobic ferments, 513.
—— liquefaction of, by bacteria, 916.
Geranium oil, Indian, 951.
Gerhardtite, crystallised basic copper nitrate, identical with, 714.
German silver, analysis of, 418.
Germination, changes in the embryo and endosperm during, Trans., 466.
—— of Jerusalem artichoke, 656.
—— of seeds, transformation of alkaloïds during the, 543.
—— of some of the Gramineæ, Trans., 458.
Githago segetum, poison of the seeds of, 1458.
Glaserite from Douglashall, 18.
Glass, gradual alteration in, produced by slight alteration of temperature, 440.
Glass, penetrability of, by water, 691, 692.
—— surfaces, influence of, on the velocity of reaction, 1208.
Glucoctonic acid, 599.
Glucoheptose, 599.
Glucolactone, d-, 1398.
Gluconic acid anilide, 155.
—— —— optical isomerides of, 1389.
—— —— phenylhydrazide, 153.
Gluconic acid, i-, 1391.
Gluconic acid, l-, 1389.
Glucosamine, benzoyl derivatives of, 578.
Glucose, destruction of, by blood and chyle, 1172.
—— conversion of, into sorbite, 1389.
—— copper solution for the estimation of, 198.
Glucose, i-, 1392.
Glucose, l-, 1391.
Glucosediphenylhydrazone, 1260.
Glucosediphenylhydrazone, i-, 1392.
Glucosediphenylhydrazone, l-, 1391.
Glucoses, benzoyl compounds of, 578.
Glucosides, benzoyl derivatives of, 578.
Glucosometer, percentage, 300.
Glutaconic acid, 737.
Glutarenediamidoxime, 126.
Glutarene diazoximediethenyl, 126.
Glutareneimidodioxime, 126.
Glutaric acids, dialkyl substituted, synthesis of, 877.
—— —— electrical conductivity of, 1038.
Gluten, crude, heat of combustion of, 938.
Glyceride-hydrolyst, Trans., 531.
Glycerol, action of sulphur on, 577.
—— commercial, assay of, 835.
—— estimation of, 198, 299.
—— estimation of, in crude glycerol, 300, 425.
—— estimation of, in soap lyes, 425.
—— estimation of, in wine and beer, 426.
—— fermentation of, 915.
—— oxidation of, with lead peroxide in alkaline solution, 20.
—— test for, 1473.
Glycerols, synthesis of, by means of hypochlorous acid, 121.
Glycines, lactones derived from, 245.
Glycocine, formation of, from chloracetic acid, 1395.
Glycogen, changes in, in the muscle during work, 185.
—— formation and fate of, 810.
—— formation of, in a muscle with an artificial circulation, 1335.
—— in the liver and muscles, 1334.
—— molecular weight of, 1215.

Glycollamine, heats of combustion and formation of, 936.
Glycollic acid, direct synthesis of, 739.
—— nitrile, 739.
—— orthotoluidide, 1161.
Glycolylorthotolylglycinamide, 245.
Glycolylphenylglycinamide, 245.
Glycolylphenylglycine, 245.
Glycuronic acid, derivatives of, 1286.
Glyoxalinedicarboxylic acid, 1439.
Glyoxalmethylphenylosazone, 24.
Gold and platinum alloys, liquation of, 947.
—— atomic weight of, 708.
—— effect of, on the freezing point of tin, Trans., 348.
—— estimation of minute quantities of, 830.
—— native, in calcite, 569.
—— potassium chloride, anhydrous, 1217.
—— sulphide, precipitated, composition of, 1217.
—— —— reactions of, 1217.
Gout, latent, Pfeiffer's test for, 401.
Grain, estimation of starch in, 928.
—— germinated, origin of the hydrolytic enzymes of, Trans., 511.
Gramineæ, germination of, Trans., 458.
Graminin, molecular weight of, 227.
Grape sugar, optical isomerides of, 1389
Graphite, different forms of, and their derivatives, 448.
—— estimation of carbon in, 923.
—— estimation of, in minerals, 923.
Graphitic oxides, 448.
Grass oils, Indian, 231.
Grasses, composition and digestibility of the proteïds of, 657.
—— seed of, existence of a cellulose-dissolving enzyme (cytohydrolyst) in the germinating seed of, Trans., 197.
Guaiacol, paranitroso-, 608.
Gum, peach, carbohydrates in, 1022.
—— straw-, 1460.
—— tragacanth, 228.
—— wood-, from straw, &c., 472.
Gum-ferments, nature of, 998.
Gyrolite from California, 343.

H.

Hæmatoporphyrin, molecular weight of, 76.
Hæmatoxylin, action of chlorine on, 905.
Hæmoglobin and oxygen, compounds of, 1450.
—— carbonic oxide, detection of, 432, 1200.
Hæmoglobin, is it present in the free state in the blood plasma of the splenic vein?, 1016.
—— heat of combustion of, 938.
—— of dog, 273.
—— of hen, 274.
Hæmoglobins, conditions of absorption of various, 182.
Hæmosiderin, 1452.
Halogens and oxygen, reciprocal displacement of, 6.
—— free, estimation of, in presence of chlorides and bromides, 825.
Haloïd salts of the alkalis, action of sulphuric acid on, in presence of some metallic salts, 289.
Hambergite, 1078.
Heart disease, nature of the effusions in, 1174.
Heat, animal, 206.
—— capacity of sulphuric acid solutions, Trans., 88—94, 160—164.
—— developed by the action of oxygen on the blood, 274.
—— development of, in electrolytes, 677.
—— of combustion of acetic acid, 100.
—— —— of formic acid, 99.
—— —— of graphitic oxides and pyrographitic oxides, 448.
—— —— of isodibutylene and isotributylene, 320.
—— —— of organic compounds, and their constitution, 1206.
—— —— of organic isomerides, 680.
—— —— of rubidium, 679.
—— —— of sulphur compounds, 1361.
—— —— of the chief nitrogenous compounds in living organisms, 937.
—— of dissolution of salt solutions, supersaturated, 1042.
—— —— of sodium phosphites and pyrophosphites, 438.
—— —— of sulphuric acid solutions, Trans., 94—114, 165—177.
—— of formation of alkaline succinates and isosuccinates, 320.
—— —— of amides, 1359.
—— —— of lithium and silver malonates, 1396, 1397.
—— —— of platinic chloride, 439.
—— —— of potassammonium and sodammonium, 319.
—— —— of sodium erythroxide, 935.
—— —— of sugars, 1360.
—— —— of uric acid and alkaline urates, 1040.
—— of fusion and solubility, relation between, 676.
—— —— of nitric peroxide, Trans., 593.

Heat of hydration of maleïc anhydride, 680.
—— of neutralisation of aluminium and beryllium fluorides, 680.
—— —— of bases, where dissociation cannot take place, 553.
—— —— of fluorides, 1.
—— of solution of a gas, 816.
—— of transformation of isomeric inosites, 1041.
—— of vaporisation, determination of, by means of the steam calorimeter, 1040.
—— production in animals, calorimetric investigations on, 182.
—— specific, of bismuth, 707.
—— —— of supersaturated salt solutions, 1042.
the theory of, and living motors, 807.
See also Thermochemistry.
Heats of combustion and dissolution of amides, 1360.
—— —— and formation of methyl salts, 101.
—— —— —— of nitrogen compounds derived from the albuminoïds, 936.
—— —— —— of nitrogenous compounds derived from albuminoïds, 936.
of urea, 306.
—— specific, experimental determination of the ratio of the, in superheated steam, 205.
Heliophyllite from Sweden, 459.
Hemipinic anhydride, Trans., 1094.
Hemp fibres, discrimination of jute fibres from, 928.
Hen, hæmoglobin of the, 274.
Hepitol, identity of, with perseïtol, 1232.
Heptamethyldihydropyrrolidine, 1432.
Heptamethylene, 727, 728.
—— amido-, 729.
Heptolactone, 589.
Heptose, 598.
Heptyl diphenyl tricyanide, 1252.
—— nitrite, normal, 353.
Heptylenic acid, 589.
Heptylic acid, γ-bromo-, 589.
Hexabenzoyl-β-inosite, 355.
Hexacetyl-β-inosite, 355.
Hexadecylene glycol, 1219.
Hexadecylene-derivatives, 1218.
Hexadecylenedicarboxylic acid, 1219.
—— anhydride, 1219.
Hexahydrophthalic acid, fumaroïd, 1282.
—— —— maleïnoïd, 1282.
—— acids, constitution of, 1277.
—— anhydride, fumaroïd, 1282.
—— —— maleïnoïd, 1283.
Hexahydroquinoline, 1320.
Hexamethylenecarboxylic acid, 738.
Hexamethylene-derivatives, geometrical isomerides of, 1386.
Hexamethylene-molecules, configuration of, 1105.
Hexamethylphloroglucinol, 1110.
Hexane, diamido-, 1001.
Hexazoxybenzene, 1117.
Hexyl alcohol, new, 473.
Hexylamine, new, 473.
Hexylbutylene, 594.
Hippuric acid, heats of combustion and formation of, 936.
Hohmannite, 456.
Homobenzenylacetoethenylazoxime, para-, 48.
Homobenzenylamidoxime, ortho-, 49.
—— para-, action of carbon bisulphide on the potassium compound of, 49.
Homobenzenylamidoximes, ortho- and para-, and their derivatives, 47.
Homobenzenylcarbonylimidoxime, para-, 48.
Homobenzenylethenylazoxime, para-, 47.
Homobenzenylethoxime salts, para-, 47.
Homobenzenylhydrazoximeamido-orthohomobenzylidene, ortho-, 255.
Homobenzoyl-orthohomobenzenylamidoxime, ortho-, 255.
Homobenzenylphenyluramidoxime, para-, 48.
Homobenzenylpropenylazoxime-ω-carboxylic acid, para-, 48.
Homobenzenylthiouramidoxime, para-, 48.
Homobenzenyluramidoxime, para-, 48.
Homobetaïnes, α- and β-, 747.
Homocinchonidine, 1166.
Homodibenzenylazoxime, ortho-, 49.
Homofluorescein, 1111.
Homofluorindine, 1145.
Homo-orthophthaleneamidimidoxime, 146.
Homopiperic acid, synthesis of, 1129.
Homoquinine, 1166.
Homoterephthalamic acid, 240.
Homoterephthalamide, 240.
Homoterephthalenediamidoxime and its derivatives, 147.
Homoterephthalenediazoximedibenzenyl, 147.
Homoterephthalenediazoximediethenyl, 147.
Homoterephthalic acid, 240.
Homoterephthalisoamic acid, 240.
Honey, eucalyptus, 122.
—— unfermentable, dextrorotatory constituent of, 356.
Hops, amount of lupulin in, 658.
—— estimation of lupulin in, 431.
Hornblende of St. Lawrence Co., New York, 1073.

Hornblende-schists near Glatz, in Lower Silesia, 1076.
Horse, chemistry of the urine of, 915.
—— respiration in, during rest and work, 392, 1170.
—— useful effect of food supplied to, 807.
Human urine, nitrogenous constituents of, 280.
Humus, estimation of, in soils, 688, 832.
—— retention of moisture by, 407.
Hunger, influence of, on the exhalation of carbonic anhydride, 1334.
Hureaulite from Branchville, 1072.
Hydantoïn, formation of, 365.
Hydrastic acid, Trans., 1095.
Hydrasteïne, constitution of, 534.
Hydrastine, 74, 532, 534, 1333.
—— constitution of, 534.
—— ferrocyanide, 1318.
—— methiodide, 532, 1167.
—— methochloride, 532.
—— methyl hydroxide, 532.
—— salts, 648.
Hydrastinemethylammonium hydroxide, 1167.
Hydratropic acid, 375.
Hydrazine, preparation of, from aldehyde ammonia, 734.
Hydrazines, 148.
—— action of chloroform and potash on, Trans., 50.
Hydrazineuracil hydrochloride, 1241.
Hydrazineuracilcarboxylic acid, 1240.
Hydrazobenzene, trinitro-, 40.
Hydrazobenzenedisulphonic acid, 987.
Hydrazobenzoic acid, meta-, acids obtained by heating, with stannous chloride, 778.
Hydrazones, action of carbon bisulphide on, 218.
Hydrindone, meta- and para-brom-, 1139.
—— metachloro-, 1139.
Hydriodic acid, influence of, on the dissolution of zinc in dilute sulphuric acid, Trans., 824.
Hydroberberine, 1011.
—— ethiodide, 1012.
—— ethochloride, 1012.
Hydrobilirubin, molecular weight of, 914.
Hydrobromic acid, preparation of, 687.
Hydrobromoxycinchine hydrobromide, 1433.
Hydrocamphorylacetic acid, 1151.
Hydrocamphorylmalonic acid, 1151.
Hydrocarbon obtained from carminic acid, constitution of, 1145.
Hydrocarbons, aromatic, action of chlorocarbonylamide, on, 156.
Hydrocarbons, cycloid, structure of, Proc., 1890, 101.
Hydrochelidonic acid, 30.
Hydrochloric acid, detection of free chlorine in, 289, 547.
—— —— decomposition of, by oxygen on exposure to light, 6.
Hydrochlorides of chlorides, 106.
Hydrocinnamaldehyde, 979.
Hydrocyanic acid, action of, on calomel, 223.
Hydrodesylphenol, Trans., 970.
Hydrofluoric acid, purification of, 687.
Hydrofluosilicic acid, titration of, 926.
Hydrofurfuran, constitution of, 730.
Hydrogen antimonide, 209.
—— arsenide, 209.
—— —— action of, on potassium permanganate, 1210.
—— carbon as an impurity affecting the estimation of the atomic weight of, 1369.
—— chloride and chlorine, estimation of, when mixed, 412.
—— —— and hydrogen in conjunction with metals, chemical equilibrium between, 685.
—— —— and water, simultaneous synthesis of, 8.
—— —— electrical conductivity of, in different solvents, 97.
—— chlorine and oxygen, equilibrium between, 8.
—— density of, 322, 330.
—— diphenyl cyanide, 1252.
—— perbromide, formation of, 6.
—— peroxide, action of, on manganese oxides, 946.
—— —— action of, on permanganic acid and the permanganates, 1062.
—— —— application of, in analysis, 419.
—— —— characteristic reaction of 1185.
—— —— conditions of the formation of, from ether, Trans., 574, 988.
—— —— formation of, from moist ether, Proc., 1889, 134.
—— —— formation of, on exposure of water to light, Proc., 1889, 134.
—— —— influence of, on the dissolution of zinc in dilute sulphuric acid, Trans., 822.
—— —— molecular weight of, 106.
—— —— spontaneous decomposition of, 106.
—— phosphide, action of, on the halogen compounds of arsenic, 1052.
—— —— combination of, with boron chloride and silicon sesquichloride, 690.
Hydrogen phosphide, combination of, with boron fluoride and silicon fluoride, 448.

Hydrogen phosphide, combination of, with silicon bromide and chloride, 559.
· liquid, 942.
—— —— spontaneously inflammable, 942.
—— solubility of, in mixtures of alcohol and water, 103.
—— sulphide, distribution of, between the metals of two dissolved salts, 1367.
explosion of, with air or oxygen, Trans., 625.
formation of, during alcoholic fermentation, 1454.
influence of, on the interaction of zinc and sulphuric acid, Trans., 821.
—— —— occurrence of, in the Stassfurt salt deposits, 336.
—— —— rhombic sulphur from, 1371.
—— —— volumetric estimation of, 290.
Hydrogenation process, characteristics of, 1304.
Hydrolysis, terminology of, Trans., 528.
Hydrolysts, Trans., 531.
Hydrolyte, Trans., 531.
Hydromuconic acid, Trans., 371, 937.
—— —— bromo-, 876.
Hydromuconic acid, $\Delta^{\alpha\beta}$-, 876.
Hydromuconic acid, $\Delta^{\beta\gamma}$-, 875.
Hydrophthalic acids, 1276.
Hydropyrogallolbenzein, 899.
Hydroquinoline, derivatives of, 177.
Hydroquinoline-1-sulphonic acid, 266.
Hydroquinoline-3-sulphonic acid, 266.
Hydroquinoline-4-sulphonic acid, 266.
Hydroresorufin, 157.
Hydrosulphides, Proc., 1890, 50.
Hydroxamic acids of the fatty series, 127.
Hydroxy-acids, α-, and their ethyl salts, action of phenylhydrazine on, 155.
Hydroxyacrylic acid, chlorobromo-, 27.
Hydroxyadipic acid, chloro-, lactone of, Trans., 910.
Hydroxyamidohydroxyquinone oxime, chloro-, 493.
Hydroxyanilidobenzoic acid, metanitropara-, 375.
Hydroxyanilidonaphthalene, 2 : 2-′, 620.
Hydroxyazo-compounds, 614.
Hydroxybenzamide, para-, reduction of Trans., 957.
Hydroxybenzidine, 59.
Hydroxybenzoic acids, action of aniline on substitution derivatives of, 158.
—— —— electrical conductivities of the ammonium and aniline salts of, 1039.
electrical conductivity of, 677.
—— — · substituted, action of aniline on, 490.
Hydroxybenzoylphosphinous acid, 618.
Hydroxybenzylacetamide, ortho-, 1111.
Hydroxybenzylamine, ortho-, 1111.
Hydroxybenzylcarbamide, ortho-, 1111.
Hydroxybenzylideneparamidodiphenylamine, 609.
Hydroxybenzylphenylcarbamide, ortho-, 1412.
Hydroxybenzylphthalimidine, para-, 487.
Hydroxycamphocarboxylic acid from camphocarboxylic acid, 638.
Hydroxycapronamide, γ-, 880.
Hydroxycitraconic acid and its derivatives, 29.
Hydroxydiketodihydropentene, tribromo-, 1272.
Hydroxydimethylethylmetadiazine, formation of, 1159.
Hydroxydimethylphenylmetadiazine, formation of, 1159.
Hydroxydiphenyl, para-, and its derivatives, 898.
Hydroxydiphenylcarbamide, ortho-, 761.
Hydroxydiphenylmetadiazine, formation of, 1159.
Hydroxydiphenylmetadiazinecarboxylic acid, 68.
Hydroxyethylbromonitropiperonylcarboxylic anhydride, Trans., 1027.
Hydroxyethylbromopiperonylcarboxylic acid, ω-, Trans., 1025.
—— anhydride, ω-, Trans., 1025.
Hydroxyethylcatecholcarboxylic anhydride, ω-, Trans., 1027.
Hydroxyethylnitropiperonylcarboxylic anhydride, ω-, Trans., 1027.
Hydroxyethylpiperonylcarboxylic acid, ω-, Trans., 996, 1020.
—— —— formation of, Trans., 1060.
—— —— fusion of, with potash, Trans., 1022.
—— —— oxidation of, Trans., 1022.
—— —— salts of, Trans., 1023.
—— anhydride, ω-, Trans., 1021.
Hydroxygluconic acid, 1399.
Hydroxy-β-halogen lactic acids, α-, distillation of with water, 736.
Hydroxyheptylic acid, 589.
Hydroxyhydromuconic acid, lactone of, Trans., 942.
Hydroxyindone, brom-, Trans., 400.
—— —— benzylamide of, Trans., 403.
—— —— hydrazone and hydrazonehydrazide of, Trans., 402.
β-naphthylamide of, Trans., 403.
Hydroxyisobutyramide, tetrachloro-, formation of, 234.
Hydroxyisobutyric acid, chloro-, distillation of, with water, 736
Hydroxyisobutyric acid, tetrachloro-, 234.
Hydroxyisoheptylic acid, 590.

Hydroxyisopropylmethylhydroxypyrimidine, 70.
Hydroxyisopropylphenylhydroxypyrimidine, 70.
Hydroxylamine, compounds of, with metallic chlorides, 558.
—— configuration of, 1263.
—— hydrochloride, 558.
—— thermochemistry of, 934.
Hydro-xylene, meta-, 1314.
Hydroxylepidine, ortho-, 1435.
—— para-, 1434, 1435.
Hydroxyl-group, influence of certain groups on the thermochemical value of, in the aromatic series, 439.
Hydroxymetadiazines, 68.
Hydroxymethyldiphenylmetadiazine, 68.
—— formation of, 1159.
Hydroxymethylethylmetadiazine, 69.
Hydroxymethylphenylethylmetadiazine, 1159.
Hydroxynaphthaquinone [2′ : 1 : 2], 628.
Hydroxynaphthaquinoneimide, chlor-, 1147.
Hydroxynaphthaquinoneoxime [2′:1:2], 628.
Hydroxy-α-naphthaquinoneoxime, β-chlor-, 1147.
Hydroxy-α-naphthyl hydroxyphenyl ketone, 389, 901.
Hydroxy-β-naphthyl hydroxyphenyl ketone, 389.
Hydroxynitropropylphthalimide, 890.
Hydroxyoxydipropionic acid, chloro-, 959.
Hydroxypentene cyanide, γγ-hexachloro-α-, 1256.
Hydroxypentenecarboxylic acid, γγ-hexachloro-, 754.
Hydroxyphenyl bisulphide, thio-, 604.
Hydroxyphenyldimethylglyoxaline, ortho-, Trans., 10.
Hydroxyphenyldimethylsuccinic acid, ortho-, 777.
Hydroxyphenyldiphenylpyrroline, ortho-, 264.
Hydroxyphenylmethylisocrotonic acid, 584.
· ortho-, 778.
Hydroxyphosphinous acids, 618.
Hydroxypropylbenzamide, β-, 860.
Hydroxypropylphthalamic acid, 472.
Hydroxypropylphthalimide, γ-, 472, 1089.
Hydroxypyrimidines, 68.
Hydroxyquinoline (kynurin), 174.
—— 1-, alkyl derivatives of, 174.
—— —— derivatives of, 265.
—— dibromo-1-, 522.
—— dibromo-3-, 523.
—— dinitro-, 523.
—— methiodides, ortho- and para-, 1323.
Hydroxyquinoline, ortho-, action of methyl iodide on, 1323.
—— tribromo-, 177.
Hydroxyquinolinedisulphonic acid, [1-], 268, 523.
Hydroxyquinolines, ortho- and para-, the halogen alkyloxides of, 1323.
Hydroxyquinolinesulphonic acid, [1-], 268.
Hydroxyquinolinesulphonic acid, [1 : 4-], 522.
—— —— bromo-1 : 4-, 522.
Hydroxyquinolinesulphonic acid, [3-], 523.
- bromo-3-, 523.
Hydroxyquinolinesulphonic acids, 268.
Hydroxyquinoneimide, chloramido-, 241.
Hydroxysulphonaphthoic acid, α-, 636.
Hydroxy-α-stilbazole, 1438.
Hydroxy-α-stilbazoline, 1439.
Hydroxytetric acid, 739.
Hydroxythymoquinone, a new, 965.
—— constitution of, 884.
Hydroxytoluic acid, symmetrical, conversion of ethyl acetoneoxalate into, 364.
Hydroxytoluyleneorthodicarboxylic acid, lactide of, 1143.
Hydroxytolyl hydroxyphenyl ketone, 389.
Hydroxytolylethylthiocarbamide, ω-, 178.
Hydroxytolylmethylthiocarbamide, 178.
Hydroxytrimethylglutaric acid lactone, 480.
Hydroxyvaleramide, γ-, 879.
Hydroxyvaleric acid, chloro-, distillation of, with water, 736.
—— acids, chloro-, 862.
Hydroxyxanthone, constitution of, 505.
Hyoscine hydrochloride, physiological action of, 1019.
Hypochlorites and ammonium salts, interaction of, Proc., 1890, 22.
Hypochlorous acid, action of light on, Trans., 622.
Hypophosphites, estimation of, 293.
Hypophosphorous acid, oxidation of, by spongy palladium, 690.
Hyposantonin, 904.
Hyposulphurous acid, influence of, on the dissolution of zinc in dilute sulphuric acid, Trans., 822.
Hypoxanthine, 534.

I.

Iceland moss, constituents of, 600.
—— spar, rate of solution of, in acids, 843.

Idocrase, analyses of, 718.
Imperatorine, reaction of, 310.
Imidothiocarbamates, 1291.
Incineration of vegetable matter, 196.
Indazole-derivatives, 781.
Indene-derivatives, formation of, from dibrom-α-naphthol, Trans., 393.
—— synthesis of, 1138.
Indian yellow, 504.
Indigo, estimation of, in dyed fabrics, 931.
—— synthesis of, from bromacetanilide, 383.
—— valuation of, 311.
Indigo-red, occurrence and detection of, in urine, 1032.
Indigotin, estimation of, for commercial purposes, 96.
Indium, effect of, on the freezing point of tin, Trans., 385.
—— oxide, action of magnesium on, 691.
Indole, acetyl-derivatives of, 988.
—— action of methyl iodide on, 1292.
—— conversion of the homologues of, into quinoline-derivatives, 1322.
—— methyl-derivatives of, 1292.
—— nitroso-, 1293.
Indolecarboxylic acid, β-, synthesis of, 1293.
Indoles, methylation of the, 1121.
—— nitro-derivatives of, 897.
—— phenylated, 57.
Indone, α-brom-, action of aniline on, Trans., 398.
—— —— preparation of, Trans., 396.
Induline, constitution of, 1265.
—— from fluorindine, 1445.
Induline-group, 908.
Indulines, 764.
Inosite, 460.
—— from Dillenburg, 345.
Inosite, α-, from quebrachite, 226.
Inosite, β-, 355.
Inosites, heat of transformation of isomeric, 1011.
—— heats of combustion and formation of, 1360.
Insolinic acid, 240.
Intercellular matter, 656.
Intestinal gases, human, methyl mercaptan in, 540.
Intestine, absorption of fat in the, 183.
—— small, absorption of sugar from, 276.
Inulin in the capitula of composites, 191.
—— reaction for, 656.
Inversion by invertase, theory of, Trans., 918.
Invertan, α-, Trans., 894.
Invertan, β-, Trans., 896.
Invertan, γ-, Trans., 901.
Invertan, δ-, Trans., 903.
Invertan, ε-, Trans., 904.
Invertan, ζ-, Trans., 908.
—— absorption-spectrum of, Trans., 912.
—— molecular weight of, Trans., 911.
Invertan, η-, Trans., 913.
Invertan-copper-compounds, Trans., 914.
Invertan-series, constitution of, Trans., 921.
Invertase, 282; Trans., 831, 896.
—— action of, on cane-sugar, Trans., 843.
—— effect of heat on solutions of, Trans., 899.
—— influence of foreign substances on the action of, on cane-sugar, Trans., 852.
—— preparation of, Trans., 869.
—— purification of, Trans., 881.
—— theory of inversion by, Trans., 918.
Iodic acid, 106, 107.
—— —— and other acids, double salts of, 107.
—— —— preparation of, Trans., 760.
Iodides, chlorides, and bromides of the alkalis, distinction between, 289.
—— estimation of, in presence of chlorides and bromides, 825.
Iodine, colour of, in solution, 446.
—— dissolved, molecular weight of, 447.
—— estimation of, 1185.
—— estimation of, in haloid salts, 1186.
—— occurrence of, in *Fucus vesiculosus* and *Chondrus crispus*, 402.
—— prolonged action of the electric discharge on, 687.
—— vapour-density of, 1365.
—— water and potassium chlorate, interaction of, Trans., 760.
Iodoform, preparation of, 577.
Iodole (tetriodopyrroline), molecular weight of, 906.
Ions, transfer of, in fused and solid silver iodide, 317.
Ipecacuanha wine, assay of emetine in, 310, 548.
Iridium, atomic weight of, 1067.
—— chloro-salts of, 1068.
—— dioxide, 918.
—— phosphochlorides, combination of, with arsenic chloride, 1069.
—— phosphorus bromides, 1383.
—— —— chlorides, 1068.
Irisin, molecular weight of, 227.
Iron and aluminium hydrated sesquioxides, relative basicity of, 1062.
—— and its alloys, electrical resistance of, at high temperatures, 549.

Iron, anomalous rotatory dispersion, in 673.
— electrochemical effects of magnetising, 678.
— electrolytic estimation of, 294.
— estimation of arsenic in, 194.
— estimation of, by means of potassium permanganate in hydrochloric acid solutions, 296.
— estimation of chromium and copper in, 85.
— estimation of free and combined carbon in, 1027.
— estimation of, in blood, 297.
— estimation of, in phosphatic manures, 420.
— estimation of, in water, 419.
— estimation of minute quantities of aluminium in, 548.
— estimation of sulphur in, 921, 1463, 1464.
— Gotz's method of estimating phosphorus in, 416.
— macro- and micro-chemical reactions of, 296.
— normal storage of, in the liver, 1177.
— ores, estimation of zinc in, 1192.
— pyrites, artificial, 338.
— quantity of, in the liver and spleen of young animals, 185.
— salts, effect of temperature on the magnetism of, 678.
— sodium sulphide, 215.
— sulphates, native, from Chili, 454, 456.
— volumetric estimation of, 924.
— volumetric estimation of, in *ferrum reductum*, 827.
— See also Ferric and Ferrous.
Isafrole, constitution and reactions of, 906.
Isinglass, heat of combustion of, 938.
Isoamyl chloroxalate, 236.
— formanilide, 758.
— phenyloxamate, 236.
— phosphite, 859.
Isoamylacetanilide, 758.
Isoamylacetic acid, 1100.
Isoamylacetoacetamide, 1097.
Isoamylaniline, 758.
Isoamylmalonic acid, 1100.
Isoamylphthalamic acid, 890.
Isoamylphthalimide, 890.
Isoamylpropargylamine, 230.
Isoanisaldoxime, 1261.
Isoapiole, bromine derivatives of, 1294.
— molecular weight of, 725.
Isobenzaldoxime, metanitro-, 1262.
Isoberberal, TRANS., 1081.
— constitution of, TRANS., 1002.
Isobornyl phenylcarbamates, 518.
Isobutaconic acid, 875.
Isobutaldehyde and succinic acid, condensation of, 589.
Isobutoxyhydrocotarnine methiodide, 532.
Isobutyl alcohol, compound of sodium hydroxide with, 1222.
— β-chloroquartenylate, 865.
— chloroxalate, 236.
— phenyloxamate, 236.
— phosphite, 859.
— trichlorolactate, 27.
Isobutylacetanilide, 758.
Isobutylacetoacetamide, 1097.
Isobutylaniline, 758.
Isobutylbenzoylecgonine hydrochloride, 913.
Isobutylbutylene, 592.
Isobutylene bromide, behaviour of sodiophenylmercaptide with, 962.
- mercaptan, 950.
Isobutylenebenzidine, 1299.
Isobutylformanilide, 758.
Isobutylglyoxalinedicarboxylic acid, 1410.
Isobutylidenediethylsulphone, 56.
Isobutylisophthalic acid, 1284.
Isobutylitaconic acid, 591, 874.
Isobutylitamalic acid, salts of, 591.
— acids, α- and β-, salts of, 592, 593.
Isobutylmetaxylene, trinitro-, 1402.
Isobutylparaconic acid, 590.
Isobutylphthalimide, 890.
Isobutyltoluene, trinitrometa-, 1401.
Isobutyric acid, electrolysis of, 1236.
Isobutyrylphenetoil, 964.
Isochloralimide, 1093.
Isocholesterin, reaction for, 1474.
Isochrysenic acid, 1313.
Isocinnamic acid, 494, 620, 1417.
— — occurrence of, in the alkaloïds of cocaïne, 494.
— chloride, 1418.
Isocitric acid, 587.
Isoctolactone, 591.
Isoctylenic acid, 591.
Isoctylic acid, γ-bromo-, 591.
Isocuminaldoxime, 1263.
Isodibenzoylcinnamene, TRANS., 707.
Isodibutylene, heat of combustion of, 320.
Isodurylamide, β-, 158.
Isodurylanilide, β-, 759.
Isoeuxanthone, constitution of, 53.
Isoeuxanthone, β-, 506.
Isoformanilide, iodo-, 1414.
Isoheptolactone, 590.
Isoheptylenic acid, 590.
— — γ-bromo-, 590.
Isohyposantonin, 905.
Isolapachone, 1310.
Isolepiden, reduction of, TRANS., 691.

Isomeric organic substances, antiseptic powers of, TRANS., 636.
Isomerides, heat of combustion of, 680.
Isomerism, dynamical, 1098.
—— geometrical, 719.
Isomethyleugenol dibromide, 967.
Isomorphism of silver nitrate with the alkali nitrates, 328.
—— of the chlorates of silver and the alkali metals, 1208.
Isomorphous mixtures, freezing point of, 1209.
Isomuconic acid, TRANS., 373.
Isonaphthylrosinduline, 910.
Isononenylenic acids, 592.
Isoparatolylrosinduline, 909.
Isophorone, 1235.
Isophthalenediamidoxime, 1447.
Isophthalic acid, 4 : 6-dichloro-, 1106.
—— —— iodo-, 1107.
—— —— trichloro-, 1106.
Isopropyl phenyloxamate, 236.
Isopropylaceranilide, 758.
Isopropylaniline, 758.
Isopropylcoumarin, thio-α-, 624.
Isopropylcoumaroxime, α-, 624.
Isopropylcoumarphenylhydrazide, α-, 624.
Isopropylformanilide, 758.
Isopropylisophthalic acid, 1283.
Isopropylitamalic acid, salts of, 590.
Isopropylmetaxylene, 1249.
Isopropylmetaxylenesulphanilide, 1249.
Isopropylmetaxylenesulphonamide, 1249.
Isopropylmetaxylenesulphonic acid, 1219.
Isopropylparaconic acid, 589.
Isopyromucic acid, identity of, with pyromucic acid, 1242.
Isosuccinic acid, brom-, action of alcoholic potash on, 1238.
—— —— heat of dissolution of, 320.
Isostilbene, derivatives of, 783.
Isotributylene, heat of combustion of, 320.
Iso-xylalphthalide, 625.
Iso-xylalphthalimidine, 625.
Isoxylepidenic acid, TRANS., 690.
Iso-xylylanilide, 759.
Itaconanilic acid, 368.
Itamalic acid, trichlor-, salts of, 586.

J.

Jacobsite from Örebrö, 1076.
Jadeite, 716.
Jarosite from Utah, 573.
Jequirity, physiological action of the active principle of, 398.
Johnstrupite, 1078.
Joints, vacuum, TRANS., 958.
Juniper, oil of, 902.
Jute-fibres, discrimination of, from flax and hemp, 928.

L.

Lactalbumin, estimation of, densed milk, 92.

Lactam formation in the fatty series, 771.

Lactarius piperatus, constituents of, 80.

Lactic acid, changes in, in the muscle during work, 185.

—— —— detection and estimation of, in wines, 1345.

—— —— formation of, from raffinose and from cane-sugar, 582.

—— —— from molasses, 583.

—— —— in urine, 188.

—— acids, chloro-, decomposition products of the sodium salts of, 1097.

Lactoisocitric acid, 587.

Lactones, 583.

—— action of ammonia on, 879.

—— action of sodium and sodium ethoxide on, 866.

—— derived from glycines, 245.

Lactonic acids, 583.

—— —— action of sodium and sodium ethoxide on the ethereal salts of, 866.

Lactose in urine, 188.

—— physiological rôle of, 186.

—— properties of, 22.

Lævoatropine, 75.

Lævotropic acid, 74.

Lansfordite, 571.

Lanthana, action of magnesium on, 693.

Lanthanum oxide, 852.

Lapachic acid, derivatives of, 1310.

—— —— oxime of, 1310.

Lapachoneoxime, 1310.

Lard, detection of cotton seed-oil and beef stearin in, 428.

—— estimation of cotton-seed oil in, 307, 428.

—— examination of, for adulteration, 93.

Laurones, 1248.

Laurone, preparation of, Trans., 981.

Lauroneoxime, Trans., 983.

Lavas, recent Vesuvian, 573.

Lead acetate, decahydrated, 862.

—— antimonate, 216

—— chloride, influence of hydrogen chloride on the solubility of, 109.

—— chromate, combustion with, 926.

—— chromates, double, 1065.

—— copper and tin, alloy of, 335.

—— effect of, on the freezing point of tin, Trans., 381.

—— electrolytic crystallisation and dimorphism of, 437.

—— electrolytic estimation of, 295.

—— estimation of in tin, 665.

—— hydrogen phosphite, 945.

—— native, from Pajsberg, Sweden, 111, 337.

—— nitrophosphite, 945.

Lead oxide raffinose, 580.

—— oxides, 699.

—— peroxide, influence of, on the decomposition of potassium chlorate, Trans., 279.

—— phosphates, 1056.

—— phosphites, 945.

—— pyrophosphite, 945.

—— separation of bismuth from, 421.

—— —— Formation and decomposition of sulphurous anhydride, 1049.

—— —— The demonstration of valency, 1050.

Legumes, soluble carbohydrates in the seeds of, 917.

Leguminosæ, cultivation of, 660.

—— fixation of free nitrogen by, 79, 814 816.

—— root tubercles of, 660.

—— the fungus symbiosis of the, 1020.

Lemon juice, estimation of citric acid in, 88.

—— oil, crystalline deposit from, Trans., 327.

Lepiden, Zinin's, constitution of, Trans., 662.

Lepidine, chloro- and bromo-, 1322.

—— ortho-(?)-nitro-, 1435.

—— paramido-, 1435.

—— substitution products of, 1434.

Lepidine-derivatives, formation of, from chinine and cinchine, 1433.

Lepidineparasulphonic acid, 1434.

Leucine, heats of combustion and formation of, 936.

Leucite, formation of, 1080.

Leucitophyre from Persia, 220.

Leucodextrin, 998.

Leucophane, 1079.
Levulinic phenylhydrazide, hydrazone of, 864.
Levulosazone, 582.
Levulose, preparation of, 1087.
—— synthesis of, 466.
Levulosecarboxylic acid, preparation of, 596.
Lichenstearic acid, preparation of, 600.
Lignic acids, 228.
Lignin of pine wood, 228.
—— quantitative reaction for, 1474.
Light, action of chlorine on water in, TRANS., 613.
—— action of, on chloric acid, TRANS., 624.
—— action of, on ether, in presence of oxygen and water, TRANS., 574, 988, PROC., 1889, 134.
—— action of, on hypochlorous acid, TRANS., 622.
—— action of, on moist oxygen, PROC., 1889, 134.
—— action of, on phosphorus, TRANS., 599.
—— action of, on silver chloride, 213.
—— action of, on the acetic fermentation, 1181.
—— and air, alteration of compounds of the benzene series when exposed to, 1401.
—— concentration of the sun's rays for chemical reactions, 1033.
—— monochromatic, production of, 549.
—— rate of decomposition of chlorine water by, 849.
Lime, gas-, estimation of ferrocyanide in, 87.
—— in tanning materials, 312.
Lime-raffinose, 580.
Limestones from the "Montagnola Senese," 712.
Limettin, TRANS., 323.
Limonetrol, 1311.
Linoleïc acid, 362.
—— —— examination of commercial oleïn for, 306.
Linseed oil, adulteration of, 1198.
Liquation of gold and platinum alloys, 947.
Liquids, increase of chemical energy at the free surface of, 328.
—— influence of capillarity and diffusion on the solvent action of, 555.
—— mixed, composition of the vapour of, 554.
—— relation of volume, pressure, and temperature in the case of, 321.
—— viscosity of, 441.
Lithium arsenate, normal, crystalline, preparation of, 10.
Lithium carbonate, detection of sodium in, 517.
—— lead chromates, 1065.
—— malonates, and their heats of formation, 1396.
—— molecular refraction of the halogen salts of, 549.
—— molybdate, rotatory power of compounds of malic acid with, 744.
—— oxide, reduction of, by magnesium, 331.
—— phosphate, normal crystalline, preparation of, 10.
—— phosphates, 1055.
Litmus, action of acids on, 792.
Liver, diastatic ferment of, 185.
—— disease, nature of the effusions in, 1174.
—— glycogen in the, 1334.
—— normal storage of iron in the, 1177.
—— of young animals, quantity of iron in, 185.
Liver-cells, proteïds of, 1014.
Lobeline, 1169.
Logwood extract, action of chlorine on, 905.
Lupins, fixation of free nitrogen by, 816.
Lupinus luteus, non-nitrogenous reserve substance of the seeds of, 284.
Lupulin, 657.
—— estimation of, in hops, 431.
Lussatite, a new form of silica, 569.
Lutecite, 712.
Lutidine, a new, 1002.
Lutidylalkine, 1447.

M.

Mace oil, 1150.
Magnesia-mica, artificial, 343.
Magnesia-knebelite from Dalecarlia, 1075.
Magnesium ammonium thiosulphate, 564.
—— as a reagent, 195.
—— atomic weight of, 850.
—— boride, 693.
—— burnt, ammonia in, 1209.
—— chromiodate, 1378.
—— effect of, on the freezing point of tin, TRANS., 381.
—— molybdate, rotatory power of compounds of malic acid with, 714.
—— nitride, formation of, 451.
—— oxide, crystalline, 850.
—— potassium arsenates, 562.
—— —— thiosulphate, 564.
—— presence of, in calcium and sodium phosphates, 664.

Magnesium, reduction of oxygen compounds by, 331, 451, 693, 1372.
—— silicates, action of sea water on, 451.
—— silicide, 1372.
—— sodium arsenates, 563.
Magnetic field, influence of, on the electrical resistance of gases, 1359.
—— rotation of phosphorous oxide, TRANS., 567.
Magnetism of salts of metals of the iron group, effect of temperature on the, 678.
Magnets iron, electrochemical effects with, 678.
Maize in the experimental plots at Grignon in 1889, 820.
Malachite, artificial formation of, 451.
Maleamic acid, dichloro-, 25.
Maleïc acid and fumaric acid, isomerism of, 363.
conversion of, into fumaric acid, 1397.
—— anhydride, heat of hydration of, 680.
Maleimide, chloramido-, 25.
—— dichloro-, derivatives of, 24.
Malic acid, combination of, with normal potassium and sodium tungstates, 1102.
—— —— estimation of, in wine, 427.
—— —— rotatory power of compounds of, with normal lithium and magnesium molybdates, 744.
—— α-dinaphthalide, 1163.
—— diorthotoluidide, 1163.
—— diparatoluidide, 1163.
—— β-naphthalide, 1163.
—— orthotoluidide, 1163.
Malonic acid, action of orthonitrocinnamaldehyde on, 163.
—— —— phenylhydrazide, 155.
Malonylphenylhydrazine, 155.
Malt, extract of, diastatic power of, 432.
Maltase, 998.
Maltose, molecular weight of, 227.
Mammals, origin of uric acid in, 184.
Manganese antimonate, 216.
—— arsenate, 563.
—— electrolytic estimation of, 294, 1029.
—— estimation of, in soils, 833.
—— ores from Dillenburg, 459.
—— oxides, 570.
—— —— action of hydrogen peroxide on, 946.
—— peroxide, action of hydrochloric acid on, PROC., 1890, 58.
—— —— constitution of, 566.
—— —— influence of, on the decomposition of potassium chlorate, TRANS., 277.
—— —— gas-volumetric estimation of, 1470.
Manganese peroxide, titration of, in Weldon muds, 548.
—— phosphorescence of, in the sulphides of the alkaline earth metals, 201.
—— potassium arsenates, 563.
—— precipitation of, as peroxide, 419.
—— preparation of, 110.
—— sodium arsenates, 563.
—— —— sulphide, 215.
—— —— thiosulphate, 12.
—— specific gravity of, 110.
—— tetrachloride, PROC., 1890, 58.
—— thiosulphate, 12, 564.
—— volumetric estimation of, 1470.
Maganiferous spring waters, 854.
Manganous acid, 1060.
Mannitol, behaviour of, towards boric acid, 1357.
—— fermentation of, 915.
—— hexachlorohydrin, 1388.
Mannitol, i-, 469.
Mannitol, l-, 467.
Mannitol-series, relation of the carbohydrates of, to α-acrose, 470.
Mannoctitol, d-, 1233.
Mannoctolactone, 598, 1232.
Mannoctonic acid, 598.
Mannoctose, 598.
Mannoctose, d-, 1232.
Mannoheptitol, 598.
Mannoheptonic acid, d-, 1230.
Mannoheptosazone, d-, 1232.
Mannoheptose, 598.
Mannoheptose, d-, 1230.
—— —— hydrazone of, 1231.
Mannonic acid and its derivatives, 225.
Mannonic acid, i-, 467.
Mannonic lactone, d-, 1233.
Mannonose, d-, 1233.
Mannose, 224.
—— acetochloro-, 226.
—— synthesis of, 466.
Mannose, d-, sugars richer in carbon from, 1230.
Mannose, i-, 468.
Mannose, l-, 466.
Mannosecarboxylic acid phenylhydrazide, 154.
Mannosediphenylhydrazone, 1260.
Mannosephenylglucosazone, i-, 468.
Mannosephenylglucosazone, l-, 466.
Mannosephenylhydrazone, i-, 468.
Mannosephenylhydrazone, l-, 466.
Manure, farmyard, analysis of, 1478.
—— —— experiments with, 411.
—— fermentation of, in absence of oxygen, 282.
Manures, estimation of the total nitrogen in, 921.
—— green, as suppliers of nitrogen, 1184.

Manures, organic, decomposition of, in soils, 1183.
—— phosphatic, estimation of ferric oxide and alumina in, 420
Manuring, effect of, with ammonium sulphate and sodium nitrate, 287.
Marsh gas fermentation, 855.
Marrow, bone-fat of, 652.
—— cattle, 1172.
Massoy bark oil, 638.
Massoyene, 638, 1316.
Matezite, 471.
—— rotatory power of, 471.
Matezodambose, 471.
—— rotatory power of, 471.
Mazapilite from North America, 218.
Medullic acid, 652.
Melamine, formation of, 1082.
Melanin, 805.
Melanins, animal, 1452.
Melezitose, 733.
Melibiose, 227, 1084.
Melibiosephenylhydrazine, 1085.
Melibiotite, 227.
Melinophane, 1079.
Melitose, 356.
Melitriose, 226, 1085.
Melting point of organic substances, exact determination of, 1.
—— points, determination of, 939.
—— —— new apparatus for estimating, 939.
—— —— of organic compounds, 1204.
Membranes, living and dead, osmosis with, 207, 277.
Menthol, action of carbon bisulphide on, 517.
Menthylxanthic acid, 517.
Mercaptans, aromatic, 603.
Mercaptomethylthiazoline, $\mu\beta$-, 860.
Mercaptopenthiazoline, μ-, 473, 1090.
Mercurammonium bromide, 1212.
—— compounds, reaction for, 1211.
—— cyanides, 223.
Mercuranisoïl oxide, 1270.
—— salts, 1270.
Mercuricobaltammonium salts, 13, 1377.
Mercurobenzamide, 1123.
Mercurodianisoïl, para-, 1269.
Mercurodimethylaniline salts, 1269.
Mercurous salts, action of sulphur on, 9.
Mercury, action of the haloïd compounds of the alkalis on those of, 1059.
—— and zinc, double cyanides of, 855.
—— —— interaction of the haloïd salts of, 224.
—— blowpipe test for, 1343.
—— compounds, aromatic, 1269.
—— cyanide, action of ammonia on the compounds of, with metallic chlorides, 351.
Mercury cyanide, action of cupric salts on, 464.
—— —— detection of, in toxicological investigations, 198.
—— detection of, in organic liquids, 926.
—— effect of, on the freezing point of tin, Trans., 383.
—— electrolytic estimation of, 294.
—— electrolytic separation of, from arsenic, molybdenum, palladium, and tungsten, 1029.
—— electrolytic separation of, from cobalt, nickel, and zinc, 664.
—— estimation of, 565.
—— hydrosulphide, Proc., 1890, 51.
—— new ammoniacal compounds of, 1211.
—— occurrence of, in tapeworms, 396.
—— oxide, action of magnesium on, 452.
—— —— influence of, on the decomposition of potassium chlorate, Trans., 279.
—— oxychloride, crystalline, 565.
—— oxysulphides, 109.
—— polarised, surface tension of, in different electrolytes, 552, 1036.
—— salts, compounds of, pyridine with, 643.
—— sensitive test for impurities in, 827.
—— solid, electrical conductivity of, 98.
—— sulphates from a furnace at Idria, 710.
Mercury-acetamide, action of iodine on, 973.
Mercury-benzamide, action of iodine on, 974.
Mesaconanilic acid, 368.
Mesaconic acid, synthesis of, from ethyl propenyltricarboxylate, 1101.
Mesitylglyoxylic acid, 981.
Mesityl methyl ketone, 981.
Mesitylpyrroline, 999.
Mesoanthramine, 1426.
—— hydride, 1426.
Messelite, 218.
Metabolism, animal, behaviour of tyrosine ethyl ether in, 187.
Metal, films of vaporised, 692.
Metallic precipitates, crystalline, 851.
Metalloquinolides, 613.
Metals, determination of the molecular weights of, 1046.
—— molecular weight of, in solution, Trans., 376, 656.
Metamorphism produced by pressure, Trans., 410.
Metapropaldehyde, 955.
Methæmoglobin, 1012.
Meteoric iron from East Tennessee, 115

Meteoric iron from Magura, Hungary, 1384.
—— —— from North Carolina, 1081.
Meteorite from Carcote, Chili, 347, 462.
—— from Mexico, 346.
—— from Mighei, Russia, 346.
—— from Phu-Hong, 222.
—— new stone, 574.
—— of Alfianello, 115.
—— of Concepcion, 115.
Methenylanilidoxime, 44.
Methose, molecular weight of, 466.
Methoxycinnamic acid, orthonitrometa-, 1127.
Methoxydihydroxydihydroquinoline, para-, 1127.
Methoxyhydrocotarnine methiodide, 531.
Methoxyl, estimation of, 299.
Methoxylepidine, para-, 1433.
Methoxymethylparaphenylenediamine, 608.
Methoxyphenyl-β-bromopropionic acid, orthonitrometa-, 1127.
Methoxyphenyllactamide, orthonitrometa-, 1128.
Methoxyphenyllactic acid, orthonitrometa-, 1127.
Methoxyquinoline-hydroxyquinoline methiodide, 174.
Methoxyquinonedioxime, 608.
Methyl alcohol, estimation of acetone in, 837.
—— amidocumate (meta-), 269.
—— anhydroberberilate, TRANS., 1039.
—— anisate, thermochemistry of, 101.
—— β-bromhydromuconate, 876.
—— bromundecylenate, 1237.
—— chloracetamidocumate (meta-), 270.
—— chloranilate, 136.
—— ω-chlorethylpiperonylcarboxylate, TRANS., 1032.
—— β-chloroquartenylate, 865.
—— chloroxalate, 236.
—— cineolate, 1314.
—— cinnamate, thermochemistry of, 101.
—— citrate, thermochemistry of, 101.
—— diacetoxypyromellitate, 984.
—— diamidopyromellitate, 987.
—— diazoacetate, action of, on the ethereal salts of unsaturated acids, 736.
—— dicyanacetate, 1395.
—— dihydrodiacetoxypyromellitate, 985.
—— dihydrodihydroxypyromellitate, 987.
—— $\Delta^{1:3}$ dihydroterephthalate dibromide and dihydrobromide, 1132.
Methyl $\Delta^{2\ 5\ \text{cistrans}}$ dihydroterephthalate di- and tetra-bromides, 1131.
—— $\Delta^{1\cdot 4}$ dihydroterephthalate tetrabromide, 1132.
—— dihydroxypyromellitate, 987.
—— diketohexamethylenetetracarboxylate (para-), 987.
—— dimethoxypyromellitate, 985.
—— dinitropyromellitate, 987.
—— dinitropyrrolinecarboxylate, 66.
—— diparatoluyl tricyanide, 1253.
—— diphenyl tricyanide, preparation of, 1252.
—— β-ethoxyquartenylate, 865.
—— ethylacetoacetate, action of ammonia on, 1097.
—— fluoride, hydrate of, 1386.
—— fumarate, thermochemistry of, 101.
—— furfuracrylate, 959.
—— gallate, thermochemistry of, 101.
—— hexamethylenecarboxylate, 737.
—— hydroxybenzoate (para-), thermochemistry of, 101.
—— imidomethylphenylthiocarbamate, 1291.
—— imidophenylthiocarbamate, 1291.
—— β-isobutoxyquartenylate, 865.
—— isophthalate, thermochemistry of, 101.
—— mellitate, thermochemistry of, 101.
—— mercaptan in human intestinal gases, 540.
—— β-methoxyquartenylate, 865.
—— methylimidomethylphenylthiocarbamate, 1291.
—— methylphenyldithiocarbamate, 1291.
—— methylphenylthiocarbamate, 1291.
—— β-naphthoate, thermochemistry of, 101.
—— nitrocumate, meta-, 269.
—— nitropyrroline-α-carboxylates, 66.
—— orthocyanobenzyl sulphide, 1250.
—— oxalacetate phenylhydrazone, 156.
—— oxalate, thermochemistry of, 101.
—— paratolyl ketone, nitroso-, 52.
—— phenylimidomethylphenylthiocarbamate, 1291.
—— phenyloxamate, 235.
—— phenylthiocarbamate, 1291.
—— phosphite, 859.
—— phthalate, thermochemistry of, 101.
—— β-propoxyquartenylate, 865.
—— α-pyrrolinecarboxylate, molecular weight of, 896.
—— quinonepyromellitate, 987.
—— succinate, thermochemistry of, 101.
—— terephthalate, thermochemistry of, 101.
—— Δ^1 tetrahydrophthalate, 1281.

Methyl Δ^{2} $^{\text{cistrans}}$ tetrahydroterephthalate dibromides, 1133.
—— trimesate, thermochemistry of, 101.
—— trimethylenetetracarboxylate, 1398.
—— undecylenate, 1237.
Methylacetanilide, 758.
—— action of zinc chloride on, 1112.
Methylacetoacetamide, 1097.
Methylallylthiocarbamide, 477.
Methylamidomethylsuccinamic acid, 870.
Methylamidosuccinamic acid, 871.
Methylanilidomaleic acid phenylimide, 379.
Methylaniline, 758.
—— orthonitro-, 612.
—— orthonitronitroso-, 612.
Methylanilines, analysis of, 309.
—— examination of, 430.
Methylanisaldoxime, 1261.
Methylanthracene, β-, 511.
Methylanthraquinone, β-, 511.
Methylasparagine, 871.
Methylaspartic acid, 871.
—— dimethylamide, 870.
Methylazophenine, 610.
Methylbenzile, para-, 168.
Methylbenzoic acid, 4 : 6-dichloro-3-, 1106.
—— sulphinide, 382.
Methylbenzylacetone, ortho-, 1138.
Methylbenzylanilinesulphonic acid, sodium salt of, 611.
Methylbenzylsulphideorthocarboxylic acid, 1251.
Methylbromacetamidocumate, bromo-, 270.
Methylbromothymol, 366.
Methylbutylphenylacetic acid, 388.
Methylcarboxyphenylacetic acid, 389.
Methyl-β-chlorocrotonic acids, α-, 958.
Methylchloropiaselenole, 973.
Methylcinchoninic acid, [3′], 1325.
Methylcinnamic acid, metachloro-α-, 1139.
—— —— metamido-ortho-, 1140.
—— —— metanitro-α-, 1140.
—— —— ortho-, 969.
—— —— para-, 969, 1140.
Methylcitraconic acid, 585.
Methylcocaïne, 647, 803, 913, 1011.
Methylcoumarin, thio-α-, 624.
Methylcoumaroxime, α-, 624.
—— acetate, α-, 624.
Methylcoumarphenylhydrazide, α-, 624.
Methylcuminaldoxime, 1262.
Methyldehydropentone, Proc., 1890, 138.
Methyldehydropentonecarboxylic acid, Proc., 1890, 138.
Methyldeoxybenzoincarboxylamide, 625.
Methyldeoxybenzoïnorthocarboxylic acid, meta-, 625.
Methyldiethylthiocarbamide, 1241.
Methyldihydrometanaphthaquinone, 388.
Methyldihydropentene methyl ketone, Trans., 232, 242.
—— —— —— pinacone of, Trans., 248.
Methyldihydropentenedicarboxylic acid, Trans., 233.
- action of bromine on, Trans., 234.
- action of hydrobromic acid on, Trans., 235.
Methyldihydropentenemethylketoneoxime, Trans., 236.
Methyldihydroquinazoline, β-, 1443.
Methyldiphenylamine, paranitroso-, 611.
Methyldiphenylene ketone oxide, 901.
Methyldiphenylmetadiazine, amido-, 68.
—— —— formation of, 1159.
Methyl-3-diphenyl-5-phenylpyrrolidone, [1-], Trans., 701.
Methyl-3-diphenyl-5-phenylpyrrolone, [1-], Trans., 698.
Methyldiphenylsulphone phenyl sulphide, 988.
Methylecgonine, 617, 913.
Methylene chloride, action of benzylamine on, 887.
—— fluoride, 1053.
—— iodide, reaction of aniline with, 1164.
Methylenedibenzylamine, 887.
Methylenedi-β-naphthyl oxide, 511.
Methylenediorthotoluidine, 888.
Methylenediparatoluidine, 887.
Methylenedi-phenylmethylpyrazolone, 646.
Methylenediphthalimide, 890.
Methylenedipiperidine, 955, 1092.
Methylenephthalyl, dichloro-, 786.
—— tetrachloro-, 786.
Methyl-2′-ethylcinchoninic acid, [3-], 1326.
Methylethylethylene glycol, δ-, oxidation of, 1222.
Methylethylhexamethylene, ortho-, Trans., 25.
Methylethylhexamethylene, synthesis of, Trans., 13.
Methylethylketol, 1235.
Methylethylnitrouracil, 32.
Methylethylpentamethylene, Trans., 150.
Methylethylphenylpyrazole, 358.
Methylethylpyridylalkine, 1436.
Methylethylsuccinic acids, symmetrical, 741.
Methylethylthiazole, 1238.
Methylformanilide, 758.
Methylfurfuraldehyde, 33.
Methylfurfurine, 1105.
Methylheptonic acid, 599.
—— lactone, 599.

Methylheptose, 599.
Methylhexamethylenemethylcarbinol, Trans., 21.
Methylhexamethylenemethylcarbinyl acetate, Trans., 22.
Methylhexose, 599.
Methylhexylitamalic acids, α- and β-, salts of, 593, 594.
Methylhexylparaconic acids, α- and β-, 593, 594.
Methylhydrasteine, 533.
Methylhydrastine, 532, 1167.
—— alcoholate, 1168.
—— hydroxide, 1168.
—— methiodide, 533, 1168.
Methylhydrazine, 23.
—— action of, on dialdehydes and diketones, 24.
Methylhydrindone, β-, 1139.
—— meta-, 1140.
—— para-, 1140.
Methylhydrindonephenylhydrazone, β-, 1139.
Methylhydroberberine, 920, 1012.
Methylhydrocinnamaldehyde, α-, 979.
—— para-, 979.
Methylhydrocinnamic acid, para-, 969.
Methylhydroxybutyric acid, α-chloro-α-, 862.
Methyl-δ-hydroxyquinazoline, β-, nitro-, and chloro-, 802.
Methylhydroxysulphonebetaïne, 522.
Methylhydroxyxanthine, 32.
Methylindene, γ-, 1138.
Methyl-α-iodoethylpentamethylene, Trans., 219.
Methylisoanisaldoxime, 1261.
Methylisobarbituric acid, 32.
Methylisobutylparaconic acids, α- and β-, 592.
Methylisoformanilide, 1258, 1414.
Methylitaconic acid, 586.
Methylitamalic acid, salts of, 585.
Methylketole, dinitro-, 897.
Methyllevulindioxime, α-, 1155.
Methylmercaptomethylthiazoline, 860.
Methylmetachlorhydrindone, β-, 1140.
Methylmetachlorophenylpropionic acid, αβ-, 1110.
Methylmetamidophenylpropionic acid, α-β-, 1110.
Methylmetanitroisobenzaldoxime, 1262.
Methylmethylenegallic acid, 530.
Methylmethylenegallocarboxylic acid, 530.
Methylmethylenetribromopyrogallol, 530.
Methylmethylenetrihydroxyphthalic acid, 530.
Methylnaphthol, 775.
Methyl-α-naphthol, β-, 776.
Methylnitrouracil, 32.
Methylnonylphenylhydrazone, 1394.
Methylorthamidobenzenylamidoxime, para-, 47.
Methylorthanisidine, 607.
—— paranitroso-, 607.
Methylorthanisidylnitrosamine, 607.
Methylorthomethoxybenzanilide, meta-, 760.
Methylorthonitrobenzamide, para-, 47.
Methylorthonitrobenzenylamidoxime, para-, 47.
Methylorthonitrobenzonitrile, para-, 47.
Methylparaconic acid, 584.
—— —— dichloro-, 587.
—— —— trichloro-, 586.
Methylparamethoxybenzanilide, meta-, 760.
Methylparatolylsulphone, bromo-, dibromo-, and dichloro-, 381.
Methylparaxylidine, 606.
Methylpentamethylenemethylcarbinol, Trans., 215.
Methylpentamethylenemethylcarbinyl acetate, Trans., 219.
—— iodide, Trans., 219.
Methylphenotetrazine, α-, 613.
Methylphenylacetylindole, [1′ : 2′ : 3′-], 24.
Methyl-3-phenyldihydroquinazolone, [2], 1443.
Methylphenylhydrazine, derivatives of, 1259.
Methylphenylindole, [1′ : 3′-], 57.
Methylphenylisocrotonic acid, α-, 665.
Methylphenylisocrotonic acid, β-, 776.
Methylphenylitamalic acid, β-, salts of 776.
Methylphenyloxazoline, βμ-, 1207.
Methylphenylparaconic acid, α-, 775.
Methylphenylparaconic acid, β, 776.
Methyl-1-phenylpyrrodiazolone, [2-], 889.
Methylphenylsemithiocarbazide, Trans., 261.
Methylphenylsulphone, bromo-, and dibromo-, 381.
—— chloro-, 380.
—— dichloro-, 381.
Methylphenylthiosemicarbazide, 23.
Methylphthalide, tetrachloro-, 786.
Methylpiazothiole, 161.
Methylpicrazide, 23.
Methylpipecolylalkine, α-, 68.
Methylpiperidine bases, β-, 1003.
Methylpropargylamine, 230.
Methylpropylene-ψ-thiocarbamide, 760.
Methylpropylglutaric acids, symmetrical, 1103.
Methylpropylmethoxybenzanilide, 760.
Methylpropylmethoxybenzoic acid, 760.
Methyl-β-pyrazole-1 : 5-dicarboxylic acid, [2], 1133.

Methylpyridinedicarboxylic acid, 1002.
Methylpyromucic acid, 601.
Methylpyrrolidonecarboxylamide, [2], 793.
Methylpyrrolketonedicarboxylic acid, tertiary, 1431.
Methylpyrrylglyoxylic acid, 1-, constitution of, 389.
Methylquinol, dinitro-, 752.
Methylquinoline, 1322.
Methylrosindone, 909
"Methylsaccharin," 382.
Methylsalicenylamidoxime, 146.
Methylsalicenylbenzenylazoxime, 146.
Methylsalicylonitrile, properties of, 146.
Methylsemicarbazide, 23.
Methylsuccinamic dimethylamide, 870.
Methylsuccinic acid, 742.
Methylstrychnine, 1447.
Methyltarconic acid, 532.
Methyltaurine, β-, 128.
Methyltaurocarbamic acid, β-, 128.
Methyltetrahydrobenzene methyl ketone, ortho-, Trans., 16.
· oxime, Trans., 18.
—— —— —— hydrazone, Trans., 20.
Methyltetrahydrobenzenemethylcarbinol, Trans., 24.
Methyltetrahydrodibutylphenanthroline, 138.
Methylthiocarbamideallyl cyanide, 1104.
Methylthiocarbamidebenzyl cyanide, 1104.
Methylthiocarbamidemethyl cyanide, 1103.
Methylthiocarbamidepropyl cyanide, 1103.
Methylthio-β-dinaphthylamine, 1306.
Methylthiophenyl - β - naphthylamine, 1307.
Methylthiophthalimidine, 1250.
Methyl-3-toluquinoline, [4′-], 1325.
Methyltolylsulphone, chloro-, 380.
Methyltribromopyrrylglyoxylic acid, [1-], 390.
Methyltriphenylbromopyrrolone, crystallography of, Trans., 728.
Methyltriphenylpyrrolone, action of bromine on, Trans., 699.
—— crystallography of, Trans., 724.
—— oxidation of, Trans., 701.
Methyluracil, alkyl derivatives of, 31.
—— diiodide, 32.
Methylxylidine, paranitroso-, 913.
——paranitrosopara-, 607.
Methylxylylenediamine, 607.
Methylxylylnitrosamine, para-, 607.
Methysticin, 257.
Methysticinic acid, 257.
Methysticol, 257.
Mica, action of solutions of alkalis, alkaline earths, and certain salts on, 1080.
Mica, analysis of, 220.
Mica-group, theory of, 460.
Michel-levite, 572.
Micrococcus acidi paralactici, 79.
Micro-organisms, reducing power of, 1453.
reduction of nitrates by, 1453.
Milk, abnormal, Trans., 201.
—— adulteration of, 128.
—— analysis, 670, 929.
—— boiled, digestibility of, 650.
—— changes in, by udder tuberculosis, 652.
—— condensed, estimation of caseïn and lactalbumin in, 92.
—— cow's, amount of nitrogen in, 652.
—— —— estimation of the principal constituents of, 1172.
—— estimation of fat in, 837.
—— in dairies, estimation of fat in, 1346.
—— influence of salts on the clotting of, 1176.
—— of the bottle-nosed whale, 812.
—— of the gamoose, Trans., 754.
—— rapid estimation of fat in, 304.
—— sour, estimation of fat in, 304.
—— volumetric, estimation of fat in, 92.
Milk-solids, extraction of fat from, 91.
Milk-sugar, carboxylic acid of, 599.
Mineral waters of Cransac, 1385.
—— —— of Malaisio, 1081.
Mineralogical-chemical theories, 219.
Minerals from the French Creek mines, 113.
—— from the Tyrol, 339.
—— of the syenite-pegmatite veins of the South Norwegian augite and nepheline-syenites, 1077.
—— solubility of, 1070.
Minium from Leadville, 570.
Molasses, extraction of raffinose from, 732.
—— lactic acid in, 583.
Molecular and atomic union, can Raoult's method distinguish between, 105.
—— constitution of compounds at their critical points, 413.
—— —— of isomeric solutions, 207.
—— forces, sphere of action of, 105.
—— refraction, 1.
—— —— of the halogen salts of lithium, sodium, and potassium, 519.
—— theory of a substance formed from two different components, 556.
—— volumes, law of, 1013.
—— —— of aromatic compounds, 683.
—— —— of organic compounds, formulæ for calculating, 323.

Molecular weight, determination of, from the reduction of vapour pressure, 323.
—— —— determinations of solid substances, 1044.
—— —— of dissolved iodine, phosphorus, and sulphur, 447.
—— —— of hydrogen peroxide, 106.
—— —— of ζ-invertan, TRANS., 911.
—— —— of metals in solution, TRANS., 376, 656.
—— —— of nitrous anhydride, TRANS., 595.
—— —— of phosphorous oxide, TRANS., 551.
—— —— of pyrroline-derivatives, 906.
—— weights, cryoscopic method of determining 321.
—— —— determination of, by Raoult's method, TRANS., 804.
—— —— new principles of determining, 1368.
—— —— of cholic acid, cholesterin, and hydrobilirubin, 914.
—— —— of hæmatoporphyrin and bilirubin, 76.
—— —— of maltose, and of several inulin-like substances, 227.
—— —— of metals, determination of, 1046.
—— —— of organic compounds, determinations of, by Raoult's method, 735.
—— —— of substances, determination of, from the boiling points of their solutions, 104.
—— —— of the colloïdal modifications of tungstic, silicic, and molybdic acids, of ferric hydroxide, &c., 1215.
—— —— of the imidoanhydrides of pyrrolinecarboxylic and indolecarboxylic acids, 67.
Molinia cœrulea, from Konigsberg, near Raibl, analysis of, 658.
Molybdenum, fluoroxy-salts of, 702.
Molybdic acid, colloïdal, molecular weight of, 1215.
Molybdiodic acid, 107.
Monazite from Quebec, 457.
—— from Ural, 571.
Moorland soil, examination of, 192.
Moradeine, 405.
Moradin, 404.
Morphine and its derivatives, physiological action of, 1178.
—— colorimetric estimation of, in opium preparations, 1349.
—— estimation of, 1198.
—— estimation of, in opium, 94, 1349.
—— ferrocyanide, 1318.
—— from *Papaver rhœas*, 616.
—— reaction of, 311.
Mosandrite, 1078.
Motors, living, and the theory of heat, 807.
Mucic acid, TRANS., 931, 937.
—— —— aldehyde-acid from, 599.
—— —— derivatives of, TRANS., 370.
Muconamic acid, β-dichloro-, TRANS., 934.
Muconamide, β-dichloro-, TRANS., 935.
Muconic acid, 877, TRANS., 375.
—— —— β-dichloro-, TRANS., 932.
—— —— —— action of reducing agents on, TRANS., 936.
—— —— dichloro-, reduction products of, 875.
Mucous fermentation, 76.
Mud from the Baku mud volcanoes, 115.
—— sea, of the alluvia of the Zuiderzee, 822.
Multi-rotation, 1081.
Muscle, changes of the glycogen, sugar, and lactic acid of the, while performing work, 185.
—— glycogen in the, 1334.
—— heat of combustion of, 938.
—— with an artificial circulation, formation of glycogen in, 1335.
Muscovite from Syra, 314.
Muscular work, influence of, on the exhalation of carbonic anhydride, 1334.
Musk, artificial, 1401.
Mussoenda coffee, 285.
Mustard oil, effect of, on animals, 539.
Myohæmatin, 652.
Myristic aldehyde, 1234.
Myristicin, 1150.
—— dibromo-, 1150.
Myrrh, 1317.

N.

Nagyágite from Nagyág, 711.
Naphtha district, the Transcaspian, 115.
Naphthabenzeïn, α-, 902.
Naphthalene, action of methyl chloride on, 1145.
—— amidochlorotrinitro-, 626,
—— anilidochlorotrinitro-, 626.
—— chlorides of, PROC., **1890**, 85.
—— —— —— action of alkalis on, PROC., **1890**, 85.
—— constitution of, 1301, 1304, 1424.
—— constitution of tri-derivatives of, PROC., **1890**, 11, 15, 16, 125, 126, 127, 128, 131.
—— 1 : 3-dichloro-, derivatives of, 626.
—— formula of, PROC., **1890**, 102.
—— picrate, molecular weight of, 725.
—— reduction of, 1146.
Naphthaleneazodihydroxynaphthalene, 1 : 2 : 2′-β-, 628.

Naphthaleneazo-β-naphthylphenylamine, α-, 993.
Naphthaleneazo-β-naphthylphenylamine, β-, 993.
Naphthalene-derivatives, comparative influence exerted by the radicles Cl, OH, and NH_2 in, on the formation of sulphonic acids, Proc., **1890**, 133.
—— hydrogenation of, 1299.
Naphthalenedisulphonic acid, α-amido-1·3′-, Proc., **1890**, 15.
Naphthalene-1 : 2′-disulphonic acid, Proc., **1890**, 125.
Naphthalene-1 : 3-disulphonic acid, action of potash on, Proc., **1890**, 136.
Naphthalenedisulphonic acids, β-chloro-, Proc., **1890**, 131.
Naphthalenes, dichloro-, the ten isomeric, and the sulphonic acids and trichloronaphthalenes derived therefrom, Proc., **1890**, 77.
—— dinitrodichloro-, 626.
—— trichloro-, homonucleal, Proc., **1890**, 76.
Naphthalene-series, isomeric change in, Proc., **1890**, 86.
Naphthalenesulphonamide, 1 : 4-, action of hydriodic acid on, 994.
Naphthalenesulphonamide, amido-, 994.
Naphthalenesulphoncyanamides, α- and β-, 501.
Naphthalenesulphonic acid, 1 : 1′-chloro-, 635.
-1 : 4-nitro-, 634.
—— —— 1 : 4′-iodo-, 168.
—— acids, chloro-, influence of position in determining the nature of the isomeric change in, Proc., **1890**, 86.
Naphthalenetrisulphonic acid, Proc., **1890**, 125.
Naphthanilide, α-, 759.
Naphthaphenanthrazine, amido-β-, 1424.
Naphthaphenazine, amido-, 509.
—— α-amido-, 1266.
—— α-amido-α-, 801.
Naphthapiazothiole, 972.
Naphthaquinol, nitro-β-, 509.
Naphthaquinoline-αγ-dicarboxylic acid, α-, 1008.
Naphthaquinoline-αγ-dicarboxylic acid, β-, 1009.
Naphthaquinolines, reduction products of, 1303.
Naphthaquinone, a third, Trans., 631.
—— dichloride, dichloro-α-, 786.
—— nitro-β-, derivatives of, 509.
Naphthaquinonedianil, 911.
Naphthaquinonedioxime, β-, 1403.
Naphthaquinone-α-oxime, chloro-β-, 1146.
—— dichloro-β-, 1147.
Naphthaquinonephenazine, 1446.
Naphthaquinonetolazine, α-, 1447.
Naphthaquinoxaline, [1 : 2-], 972.
Naphtharesorcinol, azo-colours from, 260.
Naphthasulphonamidesulphonic acid, α-, 387.
Naphthasultonsulphonic acid, ε-, 387.
Naphthazine, αβ-, preparation of, 614.
Naphthazine, symmetrical-ββ-, 993.
Naphthenylamidethoxime, β-, 62.
Naphthenylamidoximes, derivatives of the two isomeric, 62.
Naphthenylbenzenylazoxime, β-, 62.
Naphthenylcarbonylimidoxime, α-, 63.
Naphthenylcarbonylimidoxime, β-, 62.
Naphtheurhodol, α- 1266.
Naphthindole, β-, 57.
Naphthionamide, 635.
Naphthol, α-, amidothio-, 995.
—— dibrom, action of nitric acid on, Trans., 808.
—— —— preparation of, Trans., 395.
Naphthol, β-, diamido-, hydrochloride, 1424.
—— nitroso-, constitution of, 1424.
—— trinitrochloro-, 627.
Naphtholcamphorides, α- and β-, 1127.
Naphthol-ε-disulphonic acid, α-, 387.
Naphthols, action of nitrogen iodide on, 1102.
—— isomeric, dichloro-, 620.
—— nitroso-, action of sulphurous anhydride on, 1305.
—— α- and β-, reagents for, 927.
Naphtholsulphonic acids, β-, constitution of, Proc., **1890**, 11.
Naphthol-yellow, constitution of, Proc., **1890**, 16.
Naphthyl methyl ketone, 52.
Naphthylamidoacetic acid, 900.
Naphthylamine, dichloro-, 620.
Naphthylamine α-, δ-nitroso-, 630.
Naphthylamine, β-, diamido-, hydrochlorides, 1424.
Naphthylaminedisulphonic acid, α-, Dahl No. II, constitution of, Proc., **1890**, 125.
Dahl No. III, constitution of, Proc., **1890**, 16.
—— —— the Schöllkopf, constitution of, Proc., **1890**, 126.
Naphthylamine-δ-disulphonic acid, Casella's β-, constitution of, Proc., **1890**, 127.
Naphthylamine-ε-disulphonic acid, α-, 386, 388.
Naphthylamines, action of nascent nitrous acid on, 39.
Naphthylamines, β-, secondary, azo-derivatives of, 992.

Naphthylaminosulphonic acids, β-, constitution of, Proc., **1890**, 11.
Naphthylaminesulphonic acids, the isomeric heteronucleal β-, the disulphonic acids obtained by sulphonating, Proc., **1890**, 128.
Naphthylazo-α-hydroxynaphthoic acid, α-, 1118.
Naphthylcarbamide, asymmetrical, β-, 634.
Naphthyldiphenylpyrrolines, α- and β-, 263, 264.
Naphthylglycins, derivatives of, 1309.
Naphthylhydrazine, β-, 61.
—— naphthylthiocarbizinate, 61.
Naphthylhydroxythiocarbamide, α-, 1127.
Naphthylimidodiacetic acid, α-, 1309.
Naphthylimidodiacetic acid, β-, 1309.
Naphthylphenylcarbamide, amido-, 616.
Naphthylphenylene ketone oxide, α- and β-, 901.
Naphthylpiperidine, tertiary-α-, 1003.
Naphthylpiperidine, tertiary-β-, 1003.
Naphthylpropylene-ψ-thiocarbamide, α-, 160.
Naphthylrosinduline, 910.
Naphthylsemicarbazide, β-, 61.
Naphthylthiocarbizine, β-, 61.
Naphthylthiosemicarbazide, β-, 61.
Narceïne ferrocyanide, 1318.
Narcotine, 528.
—— constitution of, 531.
—— ferrocyanide, 1318.
—— oxidation of, 648.
Natrolite from Monte Baldo, 114.
Natrophilite from Branchville, 1072.
Neotesite, 1076.
Nepheline, formation of, 1080.
Nephrite, 716.
Neriin, 1316.
Nerium oleander, constituents of the bark of, 1316.
Nerves, temperature in, 536.
Nesquehonite, 571.
Nessler test, influence of temperature on, 1024.
Neurokeratin, 807.
Nickel, action of carbonic oxide on, Trans., 749.
—— antimonate, 216.
—— anomalous rotatory dispersion in, 673.
—— chromiodate, 1378.
—— effect of, on the freezing point of tin, Trans., 378.
—— electrolytic estimation of, 294.
—— electrolytic separation of cadmium, of mercury, and of silver, from, 664.
—— estimation of, 294, 297, 1470.
—— estimation of, by precipitation, as sulphide, 297.
Nickel, influence of, on steel, 566.
—— ore from Gosenbach, 711.
—— oxides, 1213.
—— oxydiammine nitrite, 216.
—— potassium arsenates, 563.
—— salts, action of sodium carbonate and bromine on solutions of, 568.
—— —— effect of temperature on the magnetism of, 678.
—— separation of zinc from, 418.
—— sesquioxide, influence of, on the decomposition of potassium chlorate, Trans., 278.
—— silicate, hydrated, from North America, 219.
—— sodium arsenates, 563.
—— —— sulphide, 215.
—— thiosulphate, 330.
Nickel-carbon-oxide, Trans., 750.
Nicotine, estimation of, in tobacco, 430.
—— influence of, on salivary secretion, 397.
—— physiological action of, 1178.
—— thermochemistry of, 101.
Nigella damascena, damasceninc from, 1317.
Niobium, microscopical test for, 86.
—— pentoxide, combinations of potassium fluoride with, 15.
Nitrates, catalytic formation of ammonia from, 689.
—— colorimetric methods for estimating, in potable waters, 831, 832.
—— elaboration of, in the plant, 1182.
—— estimation of, in water, Trans., 811.
—— formation of, in plants, 513.
—— formed in manured and unmanured soils, 408.
—— Jodlbauer's modification of Kjeldahl's method for the estimation of nitrogen in, 292.
—— molecular refraction of, 1201.
—— reduction of, by micro-organisms, 1153.
—— reduction of, by the cholera bacteria, 76.
Nitric acid and copper, conditions of the reaction between, 701.
—— —— estimation of, by diphenylamine, 415.
—— —— estimation of, by electrolysis, 1167.
—— —— estimation of, by reduction to ammonia, 1025.
—— —— estimation of, by Schulze and Tiemann's method, 1025.
—— —— influence of, on the dissolution of zinc in dilute sulphuric acid, Trans., 824.
—— —— presence and behaviour of, in plants, 1021.

Nitric oxide, preparation of, 9.
—— —— produced in the combustion of nitrogenous organic compounds with copper oxide, 292.
—— peroxide, Trans., 590.
—— —— combination of phosphorus pentafluoride with, 1052.
—— —— preparation of, Trans., 590.
—— —— physical properties of, Trans., 591.
—— —— variations in the electrical resistance of, with rise of temperature, 203.
Nitrification, 545.
—— of ammonia, 282.
Nitrifying organism, 1180.
Nitriles, polymerisation of, 1158.
—— reduction of, 1407, 1422.
Nitrites, estimation of, 193.
—— estimation of, in water, Trans., 811.
Nitroazo-compounds, reduction of, by alcoholic ammonium sulphide, 1116.
Nitrogen, amount of, in cow's milk, 652.
—— apparatus for the estimation of, in ammonium salts, 1341.
—— arrangement in space of the atoms in compounds containing, 576.
—— arrangement in space of the atoms in the molecule of carbon compounds containing, 348.
—— assimilation of, by Leguminosæ, 660.
—— atmospheric, fixation of, 545.
—— combustion of, at high pressures, 1050.
—— combustions with copper oxide, quantity of nitric oxide produced in, 292.
—— comparison of the methods of estimation of, 1466.
—— density of, 1370.
—— detection of, in organic substances, 663.
—— estimation of, in ammonium magnesium phosphate, 291.
—— free, formation of nitrous acid and ammonia from, 1051.
—— —— fixation of, 79, 814, 816.
—— fixation of, by Leguminosæ, 79.
green manures as suppliers of, 1184.
—— in organic substances, estimation of, 661.
—— in soil, influence of gypsum and clay on the conservation of, 545.
—— iodide, action of, on organic compounds, 1402.
—— isomerism of organic substances containing, 1112.
Nitrogen, Jodlbauer's modification of Kjeldahl's method for the estimation of, in nitrates, 292.
—— Kjeldahl's method of estimating, 415.
—— loss and gain of, by soil, 1023.
—— loss of, during the fermentation of nitrogenous matters, 1340.
—— loss of, in acid fodders, 1339.
—— loss of, in estimation by Will and Varrentrapp's method, 1194.
—— nitric and total, Kjeldahl's method of estimating, 1466.
—— of plants, source of, 1023.
—— preparation of, 330.
—— stereochemistry of, 1330.
—— total, estimation of, in manures, 921.
—— —— in fodders, estimation of, 1477.
Nitrogen-acids, formation of, in combustion, 447.
Nitrogen-compounds, geometrically isomeric, 1089.
stereochemically isomeric 970.
—— —— stereochemistry of, 575, 951.
Nitroprussides, 1387.
Nitroso-compounds, action of sulphurous anhydride on, 1305.
Nitrosyl chloride, absorption spectrum of, 97.
Nitrous acid, detection of, in saliva, 278.
—— —— detection of traces of, 415.
—— —— ethereal salts of, 353.
—— —— formation of, from free nitrogen, 1051.
—— —— in the atmosphere, 406.
—— anhydride, Trans., 590.
—— —— action of on substances dissolved in carbon bisulphide, 1401.
- molecular weight of, Trans., 595.
- preparation of, Trans., 591.
—— —— properties of Trans., 597.
—— compounds in sulphuric acid, test for, 922.
—— ether, spirit of, estimation of ethyl nitrite in, 927.
Nivenite, 458.
Nonyl diphenyl tricyanide, 1352.
Nonylic chloride, 1252.
Nordenskioldine, 1078.
Nosean-bearing ejections from the Laacher See, 220.
Nutmeg oil, 1150.
Nutrition of higher plants, function of ammonium salts in, 79.
Nutritive value of different albuminoids, 394.
- of wheat meal, 396.

O.

Oak-tannin, reaction of, 1275.
Oak-tannins, oxidation of, 1130.
Oats in the experimental plots at Grignon in 1889, 820.
Oat-straw, composition of, 1461.
Octacetylmelibiose, 1085.
Octacetyltetramidotriphenylbenzene, 1423.
Octohydrodiphenylfurfuran, Trans., 955.
Octose, 598.
Octyl chloride, preparation of, 577.
—— diphenyl tricyamide, 1252.
Octylbenzene, 1100.*
Octylene, 592.
Œnanthaldehyde and pyrotartaric acid, condensation of, 593.
Œnanthylidenebenzidine, 1299.
Oil, ethereal of betel leaves, 135.
—— linseed, adulteration of, 1198.
—— of birch, 256.
—— of camphor, 261.
—— of caraway, Norwegian, 902.
—— of cassia, examination of, 123.
—— of cinnamon, examination of, 423.
—— of juniper, 902.
—— of mace, 1150.
—— of mustard, amount of substances yielding, in various foods and their action on the animal body, 539.
—— of nutmeg, 1150.
—— of peppermint, Russian, 1128.
—— —— testing of, for adulterations, 199.
—— of sesame, testing, 90.
—— of wintergreen, 256.
Oil-testing, 89.
Oils, analysis of, 91.
—— apparatus for the analysis of, 671.
—— essential, analysis of, 423.
—— —— iodine absorption as a test for, 199, 307.
—— —— Maumene's test for, 834.
—— —— reactions of, 199, 200.
—— examination of, 1217.
—— fixed, reactions of, 200.
—— Indian grass, 231.
—— optical examination of, 91.
—— wool, analysis of, 305.
Oleïc acid, addition of chlorine and halogen acids to, 1396.
—— —— constitution of, 863.
—— —— process for the conversion of, into fatty acids, 863.
—— —— series, molecular weights of some members of, 737.
Oleïn, commercial, examination of, for linoleïc acid, 306.
Ononine, reaction of, 310.
Opal from John Davis River, Oregon, 337.
Opianic oxime, Trans., 1070.
Opium, estimation of morphine in, 94, 1349.
Opium-preparations, colorimetric estimation of morphine in, 1349.
Optics, chemical, studies in, with reference to the dissociation theory, 313.
Orceïn, 1105.
Orcin-aurin, 1111.
Orcinol colouring matters, 762.
—— diethyl ether, dibromo-, 1405.
—— —— —— preparation of, 1405.
Orcirufamine, 764.
Orcirufin, 763.
—— ethyl ether, 763.
Oreoselon methyl ether, 1154.
—— nitro-, 1154.
Organic compounds, detection of nitrogen in, 663.
—— —— estimation of sulphur in, 289.
—— —— formulæ for calculating the molecular volume of, 323.
—— —— isomeric, antiseptic powers of, Trans., 636.
—— —— quantity of nitric oxide produced in the combustion of, with copper oxide, 292.
—— matter in soil, exhaustion of by cropping without manures, 407.
—— substances containing copper, analysis of, 296.
—— —— exact determination of the melting point of, 1.
—— —— in alkaline solution, action of lead peroxide on, 20.
Organism, behaviour of sulphur in, 812.
Organisms, living, heats of combustion of the chief nitrogenous compounds in, 937.
—— silicic acid, as a culture medium for, 1338.
Orientation, influence of atoms or groups on, 484.
Orsat apparatus, modified, 411.
Orthoclase, formation of, 1080.
Osazones, melting points and preparation of, 581.
Osmosis with living and dead membranes, 207, 277, 1176.
Osmotic experiment, 1365.
—— pressure, kinetic nature of, 105.
—— —— nature of, 105, 441, 555, 816.
—— —— theory of, 816.
Osseïn, heat of combustion of, 938.
Ostruthin, 1151.
Oxaleneanilidoximeamidoxime, 124.
Oxaleneanilidoximeazoxime-ethenyl, 124.

Oxalenediamidoxime, 122.

—— diethyl ether, 123.

Oxalenediazoximedibenzenyl, 123.

Oxalenediazoximedipropenyldicarboxylic acid, 123.

Oxalenediuramidoxime, 124.

Oxalic acid, electrochemistry of, 100.

—— —— series, specific volumes of some ethereal salts of the, 102.

Oxalyldimethylhydrazine, 23.

Oxalylethylenephenylhydrazine, 250.

Oxanilic acid, 1124.

Oxanilyl chloride, 1124.

Oxazolines, 1267.

Oxidation in the blood, 651.

Oxides, influence, of, on the decomposition of potassium chlorate, Trans., 272.

—— mineral, synthesis of, 709.

—— more stable, behaviour of, at high temperatures, Trans., 269.

Oximes, 251, 1412.

—— isomeric, 1261.

—— —— of unsymmetrical ketones, 1263.

—— isomerism of, 1263.

—— stereochemical isomerism of asymmetrical, 1263.

Oxindole, bromamido-, 982.

Oxyberberine, Trans., 1003, 1085.

—— acetate, Trans., 1086.

—— constitution of, Trans., 1085.

Oxychlorides, metallic, formation of crystallised, 1058.

Oxycinchine, 1433.

Oxydiethylidenelactic acid, 959.

Oxygen, absorption spectra of, 675.

—— and the halogens, reciprocal displacement of, 6.

—— atomic weight of, 330, 1370.

—— density of, 322, 1370.

—— dissolved in water, estimation of, Trans., 185.

—— free, estimation of, in water, 412.

—— heat developed by the action of, on the blood, 271.

—— hydrogen and chlorine, equilibrium between, 8.

—— moist, action of light on, Proc., 134.

—— preparation from potassium ferricyanide and hydrogen peroxide, 352.

—— preparation of, in a Kipp's apparatus, 8.

—— solubility of, in mixtures of alcohol and water, 103.

Oxyhæmoglobin, stability of, 1012.

Oxyhydrastinine, synthesis of, from methyl chlorethylpiperonylcarboxylate, Trans., 997, 1034.

Oxylepiden, acicular, distillation of, Trans., 683.

Oxylepidenic acid, crystallography of, Trans., 717.

Oxyphenyldinaphthazine, 910.

Oxypyridine bases, synthesis of, 67.

Ozokerite, detection of, in beeswax, 421.

Ozone, action of, on ether, Trans., 584.

—— electrical conductivity due to the formation of, 676.

—— formation of, in combustion, 417.

—— formation of, during rapid combustion, 330.

—— production of, by flames, Proc., 1890, 26.

—— volumetric estimation of, 290.

Ozothellia nodosa, gases contained in the bladders of, 916.

P.

Palladium, atomic weight of, 17.

—— effect of, on the freezing point of tin, Trans., 380.

—— electrolytic estimation of, 831.

Palmitone, preparation of, Trans., 985.

Palmitoneoxime, Trans., 986.

Pancreas, effect of extirpation of, on the absorption of fat, 1171.

Pancreatic juice, influence of, on the colour of the dejections, 397.

Papaver rhœas, morphine from, 646.

Papaverine, action of potash on alkyl halogen-derivatives of, 179.

—— bases formed by the action of potash on the alkyl halogen salts of, 271.

Papaverinic acid, 180.

Paper, effect of various substances on the combustibility of, 1158.

—— estimation of wood fibre in, 670.

Paposite, 456.

Paracamphoric acid, 790.

Paracoumarone, 496.

Paraffin, detection of, in beeswax, 421.

—— freezing points of solutions of, 463.

Paraffins, absorption of the ultra-violet rays by derivatives of, 434.

Paragalactan, 285.

Paragalactan-like substances, 284.

Paralactic acid, formation of, during the fermentation of sugar, 78.

Paraldimine, 735.

—— amido-, 735.

Paraldol, molecular weight of, 862.

Paraldylhydrazine, 735.

Parapropaldehyde, 955.

Pargasite from Fiskernäs, Greenland, 19.

Parpevoline, 796.

Parvoline, 795.

—— Waage's constitution of, 1002.

Pathological effusions, 1173.

Peach-gum, carbohydrates in, 1022.
Peas, fixation of free nitrogen by, 814.
Peat soils, examination of, 192.
Pectic compounds in plants, 80.
Pentacetyllevulose, 732.
Pentaglucoses, estimation of, 1352.
Pentamethyldihydropyridine, 67.
Pentamethyldihydropyrroline, action of methyl iodide on, 1131.
Pentamethylene-derivatives, conversion of, into benzene, pyridine, and thiophen derivatives, 129.
Pentamethylene-ring, breaking the, 1091.
Pentamethylphloroglucinol, 1110.
Pentene, $\gamma\gamma$-octochloro-, 1256.
Pentolamide, pentachloro- 1257.
Pentose, 598.
Pentoses, estimation of, 1352.
Pentylene dibromide, γ-, 20.
—— glycol, γ-, and its anhydride, 20.
Pepper, analysis of, 95.
—— occurrence of piperidine in, 95.
Peppermint, oil of, detection of adulterations in, 1199
—— —— Russian, 1128.
Peptone, 182.
—— reactions of, 801.
Peptones, analysis of, 1351.
Peridinia, pigments of the, 1172.
Peridinia-chlorophyllin, 1173.
Peridinin, 1173.
Peridotite from Arkansas, 345.
Permanganate, standardisation of, 196.
Permanganates, compounds of ammonia with, 917.
—— metallic, action of compounds of ammonia with, 917.
Permanganic acid and the permanganates, action of hydrogen peroxide on, 1062.
Perseïtol, identity of heptitol with, 1232.
Petrographical research, evidence afforded by, of chemical change under great pressure, TRANS., 404.
Petrography of South-West Africa, 221.
Petroleum, Baku, acids poor in carbon from, 737.
—— constitution of, 223.
—— estimation of, in turpentine, 660.
—— raw, sulphur compounds in, 350.
—— residues, sulphur compounds in, 350.
Peucedanin, 1154.
Pharmacolite from the Vosges, 342.
Phaseolus vulgaris, galactan in the seeds of, 917.
Phenacetide, dinitropara-, 751.
Phenacylisoamylacetic acid, 1101.
Phenacylisoamylmalonic acid, 1100.
Phenacylmetanitroparatoluidine, 525.
Phenacylparatoluidine, 524.
Phenacylphthalimide, metanitro-, 372.
Phenallyldihydroketometadiazine, 178.
Phenamidophenol, 158.
Phenamidophenolsulphonic acid, 159.
Phenanthraquinone, action of cinnamaldehyde and ammonia on, TRANS., 11.
Phenanthrene perhydride, 637.
—— synthesis of, 515.
Phenanthraquinone, action of ammonium formate on, 781.
—— compounds of, with metallic salts, TRANS., 4.
—— mercuric chloride, TRANS., 6.
—— mercuric cyanide, TRANS., 7.
—— reduction of, PROC., 1890, 31.
—— zinc chloride, TRANS., 5.
Phenanthridine, 390.
Phenanthrone, PROC., 1890, 31.
Phenanthrylpiperidine, tertiary, 1003.
Phenethyldihydroketometadiazine, 178.
Phenethyldihydrothiometadiazine, 178.
Phenethyldiketometadiazine, 1251.
Phenetidine, dinitro-, 751.
Phenetoil, paranitro-, reduction of, 1119.
—— synthesis of ketones from, 963.
Phenetoilphthaloylic acid, 1128.
Phenol, action of nitrogen iodide on, 1102.
—— action of nitrous anhydride on, 1401.
—— action of phosphorus trichloride on, 34.
—— chlorodibromo- and bromodichloro-, and their conversion into quinone, 1108.
—— crude, examination of, 425,
—— s-dinitro-, 751.
—— dinitrometadibromo-, 1107.
—— dinitrometadichloro-, 1107.
—— estimation of, in commercial carbolic acid, 300.
—— ethers, synthesis of ketones from, by Friedel and Crafft's method, 962.
—— hemicamphoride, 1427.
—— metanitrothio-, 604.
—— monocamphoride, 1427.
—— orthamido-, action of chlorine on, 754, 1255.
—— tribromo-, action of sulphuric acid on, 883.
Phenols, action of nascent nitrous acid on, 38.
—— combination of camphor with, 1427.
—— compounds of benzotrichloride with, 901.
—— compounds of volatile fatty acids with, 488.
—— desmotropy in, 243, 1404.
—— dihydric and trihydric, physiological action of, 1019.
—— electrical conductivity of, 677.
—— iodo-, reduction products of, 1402.

Phenols, nitroso-, action of hydroxylamine on, 1403.
—— orthamido-, oxidation products of, 1444.
—— volumetric estimation of, 1473.
Phenomalic acid, trichloro-, constitution of, 365.
Phenomethyldihydroketometadiazine, 178.
—— oxidation of, 1254.
Phenomethyldihydrothiometadiazine, 178.
Phenomethyltriazine, *α*-, 149.
—— parabromo-, 152.
Phenotriazine, *α*-, 149, 613.
—— parabromo-, 152.
Phenoxycrotonic acid, *β*-, 361.
Phenoxyethylamine salts, 373.
Phenoxyethylphthalamic acid, 373.
Phenoxyethylphthalimide, 373.
Phenoxypropylene, *β*-, 362.
Phen-*α*-phenylparazoxime, 523.
Phenyl bisulphide, metanitro-, 604.
—— carbonate, reactions of, 750.
—— cyanate, preparation of, 962.
—— —— synthesis by means of, 759.
—— $\Delta^{1\ 4}$ dihydroterephthalate, 1132.
—— ethylxanthate, 603.
—— —— acetylparamido-, 605.
—— —— paramido-, 604.
—— $\Delta^{2\ \mathrm{cistrans}}$ hexahydroterephthalate, 1134.
—— *α*-naphthyl sulphide, 1292.
· phenacyl ether, metanitro-, 523.
—— phenylthiocarbamate, TRANS., 268.
—— propionate, 488.
—— salicylate, nitro-derivatives of, 1284.
—— Δ^{1} tetrahydroterephthalate, 1133.
—— $\Delta^{2\text{-}\ \mathrm{cistrans}}$ tetrahydroterephthalate, 1134.
—— thienyl ketone, stereochemically isomeric oximes of, 1294.
—— thiocyanate, 749.
—— tolylcarbamate (ortho-), 751.
—— tolylcarbamate (para-), 750.
· trithioformate, oxidation of, 988.
Phenylacetic acid, metabromodinitro-, 378.
Phenyl-*β*-acetylisocrotonic acid, *γ*-, 375.
Phenylacetylpyrazole, [1-], 798.
Phenylacetylpyrazoleoxime, [1-], 798.
Phenylacetylpyrazolephenylhydrazone, [1-], 798.
Phenylallenylamidoxime-derivatives, 41.
Phenylallenylcarbonylimidoxime, 43.
Phenylallenylethoxime nitrite, 41.
Phenylallenylphenyluramidethoxime, 42.
Phenylallenylphenyluramidoxime, 42.
Phenylallenyluramidoxime, 42.
Phenylamidoacetanilide, action of carbonyl chloride on, 1164.
Phenylamidobiazolone, 1441.
Phenylamidoethylpiperonylcarboxylic anhydride, TRANS., 1036.
Phenylammeline, 618.
Phenylamylcarbamide, 1388.
Phenylamylthiocarbamide, 1388.
Phenylangelicalactone, 377.
Phenylanilidobromomethyl-methylanilidopyrazolone, 643.
Phenylanisylethane, 1423.
Phenyl-*γ*-anisylpropylamine, *β*-, 1423.
Phenylazimidobenzene, ortho-, 1113.
Phenylazimidobenzoic acid, 374.
Phenylazimidonaphthalene, 787.
Phenylazonaphtharesorcinol, nitroso-, 261.
Phenylazophenylbiazolone, 1441.
Phenylazophenyldithiobiazolone, 1441.
Phenylazophenylthiobiazolone, 1440.
Phenylazophenyl-*ψ*-thiobiazolone, 1441.
Phenylazo-ar.-tetrahydro-*α*-naphthol, 509.
Phenylazothymol, constitution of, 884.
Phenylbenzhydrylorthobenzoic lactone, 511.
Phenylbenzoylorthobenzoic acid, 514.
Phenylbenzoylpyrazole, [1-], 798.
Phenylbenzoylpyrazoleoxime, [1-], 799.
Phenylbenzoylpyrazolephenylhydrazone, [1-], 798.
Phenylbenzylorthobenzoic acid, 514.
Phenylbenzyloxycarbamide, 1127.
Phenylbenzyloxythiocarbamide, 1126.
Phenylbromisovaleric acid, 776.
Phenylbromobutyric acid, 891.
Phenylbromoparaconic acid, 894.
Phenylbromopropionic acid, orthonitrometachloro-, 1127.
Phenylbromopyrazole, [1-], 797.
Phenylbromopyrazoledicarboxylic acid, 1165.
Phenylbutene-*α*-hydroxy-*ω*-dicarboxylic acid, orthonitro-, 163.
Phenylbutine methyl ketone, paranitro-, 162.
Phenylbutinecarboxylic acid, paranitro-, 162.
Phenylbutine-*ω*-dicarboxylic acid, orthonitro-, 163.
Phenylbutylene, 777.
Phenylbutyrolactone, action of halogen acids on, 891.
Phenylcarbizinecarboxylic acid, amido-, 1441.
Phenylchlorobutyric acid, 891.
Phenyl-*β*-cinnamenylacrylonitrile, *α*-, 1408.
Phenylcrotonic acid, *α*-thio-, 362.
—— —— *β*-thio-, 361.

Phenyldehydrohexonecarboxylic acid, Trans., 308.
Phenyl-γδ-dibromethyl-β-bromacrylic acid, 162.
Phenyldibromopropenylethoxime chloride, 42.
Phenyldibromopyrazole, [1-], 797.
Phenyldichlorohydroxypyridonecarboxylic acid, 965.
Phenyldihydroquinazoline, 72.
Phenyldimethylbromopyrazole, 1165.
Phenyldimethylglyoxaline, Trans., 9.
Phenyldimethylquinolylthiocarbamide, 1005.
Phenyldiketomethylanilidobromopyrrolidine, 642.
Phenyldiketomethylanilidodibromopyrrolidine, 642.
Phenyldiketomethylanilidodichloropyrrolidine, 643.
Phenyl-β-dinaphthylcarbamide, 634.
Phenyldisazothymol, constitution of, 884.
Phenyldithienyl, 1420.
—— dinitro-, 1421.
—— tribromo-, 1420.
Phenyldithienyldisulphonic acid, 1421.
Phenylene bisulphide, para-, 605.
Phenyleneamidinebenzenylorthocarboxylic acid, 970.
Phenylenediamine, meta-, preparation of, from resorcinol, 245.
—— ortho-, oxidation of, 800.
Phenylenediamines, condensation of, with acetaldehyde, 139.
—— condensation of, with butaldehydes, 138.
Phenylenenaphthylenemethane oxide, β-, 901.
Phenylenepyridineketonedicarboxylic acid, α-, 1008.
Phenylenepyridineketonedicarboxylic, acid, β-, 1009.
Phenylenepyridineketonedicarboxylic acids, formation of, by the oxidation of naphthaquinoline derivatives, 1007.
Phenylenequinaldine, amido-, 1298.
Phenylethoxythiocarbamide, 1126.
Phenylethylhydrazine, orthamido-, 612.
Phenylfurfuracrylonitrile, α-paramido-, 1408.
—— α-paranitro-, 1408.
Phenylglycinparatoluidide, 1285.
Phenylglycuronic acid, 1286.
Phenylglyoxal, 51.
Phenylglyoxalinedicarboxylic acid, 1440.
Phenylglyoxylic acid, orthonitro-, isomeric hydrazones of, 1117.
—— —— stereochemically isomeric oximes of, 1274.
Phenylglyoxylic hydrazone, orthonitro-, 1117.
—— —— metanitro-, 1117.
—— methylphenylhydrazone, ortho-, 1118.
Phenylhexamethylene, derivatives of, Trans., 304.
—— methyl ketone, Trans., 320.
—— —— —— oxime. Trans., 321.
Phenylhexamethylenecarboxylic acid, Trans., 316, 322.
Phenylhexamethylenedicarboxylic acid, Trans., 315.
Phenylhydrazides, formation of, 152.
Phenylhydrazido-α-hydroxybutyric acid, pseudo-, and its derivatives, 155.
Phenylhydrazidomandelic acid, pseudo-, 156.
Phenylhydrazine, action of, on the skin, 582.
—— inorganic derivatives of, 617.
—— metanitro-, 150.
—— orthonitro-, 148.
—— parabromorthonitro-, 151.
—— β-phthalylphenylhydrazinate, 1327.
—— pyrocinchonylphenylhydrazinate, 1327.
Phenylhydrazines, nitro-, action of heat on, in presence of various liquids, 40.
—— symmetrical nitro-, of the aromatic series, 40.
Phenylhydrazonelevulinic acid and anhydride, paranitro-, 41.
—— anhydride, 70.
Phenylhydrazonepyruvic acid, paranitro-, 41.
Phenylhydrazones, 40.
Phenylhydrazophenylbiazolone, 1441.
Phenylhydrazophenyldithiobiazolone, 1441.
Phenylhydrazophenylthiobiazolone, 1441.
Phenyl-γ-hydroxybutyramide, 890.
Phenyl-β-hydroxy-α-isoamylethylmalonic acid, β-, 1101.
Phenylhydroxypyrimidinecarboxylbenzamidine, 69.
Phenyl-α-hydroxysuccinic acid, α-, 1135.
Phenyl-α-hydroxysuccinic acid, β-, 1136.
Phenylhydroxythiocarbamide, 1126.
Phenylhydroxyvaleric acid, salts of, 776.
Phenylimidophenyl, 490.
Phenylindole, 3′-, reactions of, 57.
Phenyliodobutyric acid, 891.
Phenyl-α-isoamylbutenyllactone, γ-, 1101.
Phenyl-α-isoamylbutyrolactone, β-, 1101.
Phenylisobromoparaconic acid, 895.

Phenylisocrotonic acid, chloro-, 620.
—— —— α-thio-, 362.
—— acids, dichloro-, isomeric, 620.
Phenylisocyanuric acid, 618.
Phenylisophthalic acid, 1284.
Phenylisovalerolactone, 776.
Phenylitaconic acid, 894, 895.
Phenylizinedihydroxytartaric acid, metanitro-, 151.
Phenylketodihydroquinazoline, 72.
Phenylketohydrazodihydroquinazoline, 72.
Phenyllactamide, orthonitrometachloro-, 1127.
Phenyllactic acid, orthonitrometachloro-, 1127.
Phenyl-β-lactic acid methyl ketone, orthonitrometachloro-, 1128.
Phenylmaleïc acid, 1136.
—— anhydride, 1136.
Phenylmalic acid, 1135.
Phenylmalic acid, α-, 1135.
Phenylmalic acid, β-, 1136.
Phenylmetanitroparatolylcarbamide, 760.
Phenylmethoxythiocarbamide, 1126.
Phenylmethylacetonylhydroxypyrimidine, 70.
Phenylmethylbiazoline, 1442.
Phenylmethylchloropyridazone, 71.
Phenylmethyldichlorobiazolone, 1441.
Phenylmethylethoxypyridazone, 71.
Phenylmethylhydrazine, orthamido-, 613.
Phenylmethylhydroxypyridazone, 71.
Phenylmethylhydroxypyrimidineacetic acid, 69.
Phenylmethylhydroxypyrimidinepropionic acid, 70.
Phenylmethylimidobiazole, 1442.
Phenyl-β-methylpiperidine, orthoparadinitro-, 1004.
—— —— paranitro-, 1003.
Phenylmethylpropylene-ψ-thiocarbamides, 159.
Phenylmethylpyrazole, 71.
Phenylmethylpyrazolecarboxylic acid, 71.
Phenylmethylpyrazolone, thio-, 796, 1269.
Phenylmethylpyrazoloneazobenzene, 29.
Phenylmethylpyrazoloneketophenylhydrazone, 28.
Phenylmethylpyridazone, 71.
Phenyl-β-methyltaurocarbamic anhydride, 159.
Phenylmethyltriazolecarboxylic acid, oxidation of, 1165.
Phenyl-β-naphthindole, [2′-], 57.
Phenyl-β-naphthindole, [3′-], 57.
Phenylnaphthylamine, amido-, action of nitrous acid on, 785.
Phenyl-α-naphthylamine, thio-, 1307.
Phenyl-β-naphthylamine, azo-derivatives of, 990.
—— —— thio-, 1307.
Phenylnaphthylamine-blue, 1308.
Phenyl-β-naphthylcarbamide, asymmetrical, 633.
—— —— chloride, 633.
Phenyl-α-naphthylcarbazole, 1307.
Phenylnitrososulphone, 781.
Phenylorthamidotolylcarbamide, 760.
Phenylorthobenzylenediamine, 1258.
Phenylorthonaphthylenediamine, α-631.
Phenylorthotolyldichlorodiketoparadiazine, 526.
Phenylorthotolyldiketodihydroparadiazine, 270.
Phenylorthotolyl-$\alpha\gamma$-diketopiperazine, 1286.
Phenylorthotolylsemithiocarbazide, TRANS., 259.
Phenyloxazoline, μ-, 1267.
Phenylparachlorophenylhydrazine, α-dinitro-, 1119.
Phenylparaconic acid, 621.
—— —— bromo-, 895.
—— acids, dichloro-, isomeric, 619.
Phenylparamidotoluene, orthonitro-, 1113.
Phenylparatolylamine, 609.
Phenylpentamethylene bromide, TRANS., 313.
—— glycol, 311.
Phenylphenylhydrazine, orthoparadinitro-, derivatives of, 1259.
Phenylphosphoryl dichloride, 34.
—— tetrachloride, 35.
—— thiochloride, 35.
Phenylpropylene, α-thio-, 362.
Phenylpropylene-ψ-thiocarbamide, 159.
Phenylpseudohexylcarbamide, symmetrical, 474.
Phenylpseudohexylthiocarbamide, symmetrical, 474.
Phenylpyrazole, derivatives of, 1164.
Phenylpyrazoledicarboxylic acid, 1164.
Phenylpyrazolonecarboxylic acid, 156.
Phenylquinazoline, 1442.
Phenylquinonediimide, 609.
Phenylrosinduline, 909.
—— amido-, 765.
Phenylsalicylic acid, 892.
—— —— dinitro-, 893.
—— —— tribromo-, 893.
Phenylsuccinazone, 1120.
Phenylsulphonacetone, 780.
Phenylsulphonamic acid, 1137.
Phenylsulphone-α-bromopropionic acid, α-, 381.
Phenylsulphonepropionic acid, α-, 381.
Phenyltetrahydroquinazoline, 73.

Phenylthiazoline, 524.
Phenylthiocarbamide, 1291.
—— action of allyl bromide on, Trans., 301.
—— action of benzyl chloride on, Trans., 295.
Phenylthiocarbamideallyl cyanide, 1104.
Phenylthiocarbamidebenzyl cyanide, 1104.
Phenylthiocarbamideethyl cyanide, 1104.
Phenylthiocarbamidemethyl cyanide, 1104.
Phenylthiocarbamidepropyl cyanide, 1104.
Phenylthiophen and its derivatives, 134.
Phenylthiophensulphonic acids, 134.
Phenylthiouramidocinnamic acid, ortho-, 1123.
Phenyltoluquinoxaline, constitution of, 525.
Phenyltolylamine, paramido-, 610.
—— paranitroso-, 609.
Phenyltriazolecarboxylic acid, 1166.
Phenyltriazoledicarboxylic acid, 1165.
Phenyltribromopyrazole, [1-], 797.
Phenyltrichloropyridone, 965.
Phenyltrichloropyridonecarboxylic acid, 965.
Phenyltrimethylmethane, amido-derivatives of, 1296.
—— —— nitro-derivatives of, 1296.
Phillipsite from Somoskö, 718.
Philothion, 905.
Phleïn, molecular weight of, 227.
Phloridzin diabetes, 1336, 1337.
Phloroglucinol, 136.
—— acetate, tribromo-, 1109.
—— action of bromine on, 1108.
—— action of chlorine on, 488.
—— methyl-derivatives of, 1110.
—— physiological action of, 1019.
—— tribenzoate, 136.
Phonolites from Colorado, 1075.
Phorone, 769.
Phoronepyrroline, 1000.
Phosphates, natural, analysis of, 293.
Phosphonium sulphate, 9.
Phosphorescence of copper, bismuth, and manganese in the sulphides of the alkaline earth metals, 201.
Phosphoric acid and boric acid, a derivative of, 108.
—— —— estimation of, in presence of silica, 825.
—— —— estimation of, in slags, 292.
—— —— in soil, exhaustion of by continuous cropping without manures, 407.
Phosphoric acid of mineral origin, recognition of, 83.
—— —— separation of vanadic acid from, 1343.
—— —— the citrate method of estimation of, 416.
Phosphorites from the Government of Smolensk, 1071.
Phosphorous acid, ethereal salts of, 558.
—— oxide, Trans. 545.
—— —— action of chlorine on, Trans., 572.
—— —— action of heat on, Trans., 552.
—— —— action of light on, Trans., 552.
—— —— action of oxygen on, Trans., 569.
—— —— action of ozone on, Trans., 571.
—— —— action of water on, Trans., 567.
—— —— crystallography of, Trans., 554.
—— —— dispersion of, Trans., 566.
—— —— magnetic rotation of, Trans., 567.
—— —— molecular weight of, Trans., 551.
—— —— physiological action of, Trans., 573.
—— —— refraction equivalent of, Trans., 564.
—— —— relative density of, Trans., 557.
—— —— specific volume of, Trans., 558.
—— —— thermal expansion of, Trans., 560.
Phosphor-tin, estimation of phosphorus in, 83.
Phosphorus, action of light on, Trans., 599.
—— amorphous, properties of, Trans., 599.
—— dissolved, molecular weight of, 447.
—— estimation of, in phosphor-tin, 83.
—— in iron, Götz's method of estimating, 416.
—— odour of, Trans., 573.
—— pentafluoride, combination of, with nitrogen peroxide, 1052.
—— specific volume of, Trans., 562.
—— total, estimation of, in urine, 825.
—— trichloride and oxychloride, method of distinguishing, 664.
Phosphosiderite, 1073.
Phosphotrimetatungstic acid, 704.
Phosphovanadates, 1067.

Photobacterium phosphorescens, 998.
Photographic plate, measurement of the relative density of the deposit on, 933
Phthalaldehydic acid, action of orthodiamines on, 969.
Phthalamidodiphenylamine, 609.
Phthalanilphenyl phenylcarbamate, 761.
Phthalic acid, reduction products of, 1275.
Phthalimides, substituted and their conversion into the corresponding amines, 890.
Phthalimidine, derivatives of, thio-, 1250.
Phthalimidopropiophenone, 372.
Phthalodiphenyline, 167.
Phthalylchloracetic acid, 785.
Phthalyldiethylbenzidine, 1297.
Phthalylorthamidoquinoline, 1324.
Phykopyrrin, 1173.
Physiological action and chemical constitution, relation between, 280.
—— —— and optical properties of inorganic substances, parallelism between, 813.
—— —— of hyoscine hydrochloride, 1019.
—— —— of morphine and its derivatives, 1178.
—— —— of phosphorous oxide, TRANS., 571.
—— —— of pituri and nicotine, 1178.
—— —— of related chemical compounds: toluidines and phenols, 1018.
—— —— of selenious acid, 542.
—— —— of sulphonal, 542.
—— —— of thallium salts, 1452.
—— —— of the active principle of jequirity, 398.
—— —— of the cresols, 813.
—— rôle of lactose, 186.
Physiology of tannins, 186.
Phytosterin, 74, 649.
Piaselenole, 160.
—— amido-, 161.
Piaselenoles, 972.
Piazothiole, 161.
Piazothioles, 972.
Picoline, *β*-, new synthesis of, 1394.
—— the second, 1432.
Picolylalkine, *α*-, 67.
Picolylethylalkine, *α*-, 1436.
Picolylfurylalkine, *α*-, 1437.
Picolylmethylalkine, *α*-, 68.
Picraena excelsa, constituents of, 791.
Picrasmic acid, 792.
Picrasmin, 792.
Picric chloride, action of, on ethyl sodacetoacetate, 1418.
Picrylmetachlorophenylhydrazine, 1119.
Picryl-*α*-naphthylhydrazine, 40.
Picrylorthotolylhydrazine, 10.
Picrylparachlorophenylhydrazine, 1118.
Picrylparatolylhydrazine, 40.
Picrylphthalimide, 374.
Pig, digestion in the, 153.
Pigments of the *Peridinia*, 1172.
Pilocarpine ferrocyanide, 1318.
Pinacoline, oxidation of, 237.
Pinene, 1315.
—— constitution of, TRANS., 964.
Pinite, *β*-, 244.
Pinole and its derivatives, 169.
—— nitrosochloride, 170.
Pinoleglycol ethyl ether, 170.
Pinolenitrolamine, 170.
Pinolenitrolaniline, 170.
Pinolenitrolbenzylamine, 170.
Pinolenitrol-*β*-naphthylamine, 170.
Pinolenitrolpiperidine, 170.
Pinus abies, terpene from, 789.
Pinus cembra, dextrorotatory terpene from, 789.
Pipecolylalkine, *α*-, 67.
Pipecolylethylalkine, *α*-, 1436.
Pipecolylfurylalkine, *α*-, 1437.
Pipecolylmethylalkine, *α*-, 68.
Piperazine group, stereochemical studies in, 1331.
Piperic acid, oxidation of, 1274.
—— —— synthesis of, 1129.
Piperidine and alcohol, products of the action of heated zinc-dust on, 1429.
—— and other basic substances, equilibrium between, 1363.
—— bases, 1002.
—— —— synthesis of, 67.
—— occurrence of, in pepper, 95.
—— thermochemistry of, 101, 1363, 1368.
Piperidylrhodamine, 1003.
Piperon, 80.
Piperonylketonic acid, 966.
Pituri, physiological action of, 1178.
Piuri, 504.
Plagioclase, artificial formation of, 718.
Plant, elaboration of nitrates in the, 1182.
—— importance of chlorine in the, 1182.
Plants, ammonia in the nutrition of, 287.
—— boric acid in, 656.
—— calcium oxalate crystals in, 1182.
—— cholesterin in, 1457.
—— diffusion of alumina in, 818.
—— green, assimilation of carbon from certain compounds by, 818, 1021.
—— fat-decomposing ferments in, 1455.
—— formation of calcium oxalate in, 191.
—— formation of nitrates in, 543.

Plants, function of tannin in, 819.
—— higher, function of ammonium salts in the nutrition of, 79.
—— influence of acids on the evolution of gases by, 190.
—— influence of the composition of the soil on the physical properties of, 81.
—— occurrence of boron in, 1338.
—— pectic compounds in, 80.
—— presence and behaviour of nitric acid in, 1021.
—— rôle of potassium in, 917.
—— source of nitrogen of, 1023.
Plant-shoots, etiolated, formation of cane-sugar in, 282.
Platinic chloride, heat of formation of, 439.
Platinum black, very active, preparation of, 453.
—— and gold alloys, liquation of, 947.
—— tetrafluoride, 217.
Platososemiamine chloride, 1218.
Plattnerite from Idaho, 339.
Pleonectite from Sweden, 112.
Pleurasite, 1076.
Pleurisy, nature of the effusion in, 1173.
Pogonopus febrifugus, constituents of the bark of, 404.
Poison of corn cockle seeds, 1458.
Poisoning cases, detection of mercuric cyanide in, 198.
Polarisation, circular, of certain tartrate solutions, 313.
—— maximum, of platinum electrodes in sulphuric acid, 316, 551, 675, 676.
—— of electrodes, 933.
—— of platinum electrodes in dilute sulphuric acid, 316, 551, 675, 676.
Polyazo-compounds, 1118.
Polycrase from California, 854.
Polygalic acid, 262.
Poppy cake, estimation of fat in, 306.
Porcelain, Chinese, rocks used in the manufacture of, 461.
—— constitution of, 1074.
Porphyrite bosses in New Jersey, 345.
Potassammonium, 210, 450, 560, 679.
—— heat of formation of, 319.
Potassium aluminium silicates, 13.
—— ammonium thiosulphate, 564.
—— and sodium chlorides, simultaneous solubility of, 103.
—— —— —— solubility of mixed, 442.
—— antimony tartrate, circular polarisation of, 313.
—— arsenate, action of, on sesquioxides, 1377.
—— aurochloride, anhydrous, 1217.
—— beryllate, 698.
—— borotartrate, circular polarisation of, 314.
Potassium bromide and chloride, solubility of mixed, 443.
—— —— and iodide, solubility of mixed, 443.
—— cadmium thiosulphates, 1057.
—— carbonate and hydroxide, reduction of, by magnesium, 332.
—— chlorate, influence of different oxides on the decomposition of, TRANS., 272.
—— —— iodine, and water, interaction of, TRANS., 760.
—— chloride and iodide, solubility of mixed, 443.
—— chromiodate, 107.
—— combination of ammonia with, 209.
dichromate, influence of, on the decomposition of potassium chlorate, TRANS., 280.
—— estimation of, in soils, 668.
—— ferricyanide, preparation of, 352.
—— preparation of oxygen by aid of, 352.
volumetric estimation of, 831.
—— ferrocyanide, non-poisonous nature of, 281.
—— fluoroxyhypomolybdate, 703.
—— hydrogen malonate, 740.
sulphate, new hydrate of, 450.
tartrate, estimation of, in wine, 427.
—— hydroxide, vanadium in, 706.
—— iodide, solubility of, 443.
—— —— solutions, decomposition of, by oxygen and light, 7.
—— in urine, estimation of, as hydrogen potassium tartrate, 187.
—— iridosochloride, 1068.
—— lead chromates, 1065.
—— molecular refraction of the halogen salts of, 549.
—— molybdoiodate, 107.
—— nitrate, influence of, on the decomposition of potassium chlorate, TRANS., 282.
—— nitrosoplatinochloride, 709.
—— pentathionate, 1210.
—— permanganate, action of hydrogen arsenide on, 1210.
—— —— gas-volumetric estimation of, 1468.
—— —— influence of, on the decomposition of potassium chlorate, TRANS. 280.
—— plumbate, 109.
—— propionate, electrolysis of, 1236.
—— pyroxyhexathiovanadate, 1381.
—— quadromalonate, 740.
—— quadroxalate, 740.

Potassium rhodium chloride, 1383.
—— —— nitrite, 1382.
—— rôle of, in plants, 917.
—— silicofluoride, 694.
—— succinate, heat of formation of, 320.
—— sulphate, reduction of, by hydrogen and carbon, 1053.
—— sulphatoiodate, 107.
—— sulpho-α-naphthyl bisulphide, 606.
—— —— ethylxanthate, 606.
—— sulpho-β-naphthyl bisulphide, 606.
—— —— ethylxanthate, 606.
—— tetrathionate, 1210.
—— tungstoiodate, 107.
—— urate, thermochemistry of, 1040.
Potato, sweet, carbohydrates in, 1022.
Potatoes, experiments at Rothamsted on the growth of, 409.
—— in the experimental plots at Grignon, in 1889, 820.
Potato-shoots, solanidine in, 1182.
Potential, fall of, at the cathode, in Geissler's tubes, 1035.
—— difference of, between two dilute solutions of binary electrolytes, 1355.
Precipitation, 847.
Pressure, effect of, on chemical action, Trans., 408.
—— osmotic, theory of, 846.
—— volume and temperature, relation of, in the case of liquids, 321.
Propaldehyde and propaldehyde-ammonia, pyridine-derivatives from, 794, 1002.
—— and succinic acid, condensation of, 587.
—— α-dichloro-, 955.
—— polymeric modifications of, 955.
—— tribromo-, 861.
Propane hydrate, 1386.
Propargylamine and its derivatives, 229.
Propenylbenzene-derivatives, conversion of allylbenzene-derivatives into, 748.
Propenyltoluyleneamidine, 1115.
Propiolic acid, bromo-, action of aromatic amines on, 371.
—— acids, substituted, 27.
Propionamide, thermochemistry of, 1360.
Propionic acid, bromodichloro-, 27.
—— —— electrochemistry of, 100.
—— —— electrolysis of, 1236.
—— —— tetrachloro-, 27.
—— —— tribromo-, 861.
—— anhydride, α-dichloro-, 1328.
—— —— —— action of phenylhydrazine on, 1327.
Propionitrile, action of, on chlorides of fatty acids, 726.
—— solid α-dichloro-, molecular weight of, 726.
Propionylanisoïl, para-, 963.
Propionylbenzoic acid, orthopentachloro-, 785.
Propionylchlorodibromophenol, 1108.
Propionylmetadiethoxybenzene, 964.
Propionyl-α-naphthyl methyl ether, 964.
Propionylnitrodibromophenol, 1107.
Propionylphenetoil, 964.
Propionylphenylhydrazine, 1328.
Propionylpropaldehyde, 357.
Propiophenone hydrochloride, amido-, 372.
Propyl acetate, α-dibromo- and α-dibromo-, 1084.
—— alcohol, normal, compound of calcium chloride with, 465.
—— benzoate, δ-amido-, 1268.
—— β-chloroquartenylate, 865.
—— chloroxalate, 236.
—— β-ethoxyquartenylate, 865.
—— hydrogen sulphate, γ-amido-, 473.
—— β-isobutoxyquartenylate, 866.
—— β-methoxyquartenylate, 865.
—— phenyloxamate, 235.
—— phosphite, 859.
—— β-propoxyquartenylate, 865.
—— trichlorolactate, normal, 27.
Propylacetanilide, 758.
Propylallylthiocarbamide, 476.
Propylamine, β-bromo-, derivatives of, 859.
—— derivatives of, 172, 1089.
—— di- and tri-bromo-, 228, 229.
—— hydrobromide, γ-bromo-, 1090.
Propylammonium propyldithiocarbamate, 476.
Propylaniline, 758.
Propylbenzamide, β-bromo-, 860.
—— β-chloro-, 1268.
Propylbenzene, action of chromyl chloride on, 978.
—— nitration of, 982.
Propylbenzenes, ortho- and para-bromo-, 503.
Propylbenzenesulphonic acids, normal, 503.
Propylbenzoyldextroecgonine hydrochloride, 913.
Propylene, amido-, 860.
—— bromide, action of ammonia on, 952.
—— mercaptan, 950.
—— thiocyanate, 950.
—— selenocyanate, 950.
Propylenecarbamide, 128.
Propylene-ψ-carbamide, 859.
Propylenediphenylsulphone, 988.
Propyleneoxidecarboxylamide, trichloro-, 234.
Propylene-ψ-selenocarbamide hydrobromide, 880.

Propylenethiocarbamide methiodide, 128.
Propylene-ψ-thiocarbamide, 127, 859.
Propylethylthiocarbamide, 476.
Propylformanilide, 758.
Propylhexamethylene, 1320.
Propylidenediethylsulphone, 56.
Propylisobutenyltricarboxylic acid, 1103.
Propylitaconic acid, 589.
Propylitamalic acid, salts of, 588.
Propylmercaptomethylthiazoline, 860.
Propylmercaptophthalimide, 472.
Propylmetachlorotoluene, para-, sulphonic derivatives of, 779.
Propylmetaxylene, 1249.
Propylmetaxylenesulphanilide, 1249.
Propylmetaxylenesulphonamide, 1249.
Propylmetaxylenesulphonic acid, 1249.
Propylmethylthiocarbamide, 476.
Propylortho-xylene, 1249.
—— tribromo-, 1249.
Propylortho-xylenesulphanilide, 1249.
Propylortho-xylenesulphonamide, 1249.
Propylortho-xylenesulphonic acid, 1249.
Propylparaconic acid, 588.
Propylparaxylene, 1249.
Propylparaxylenesulphanilide, 1249.
Propylparaxylenesulphonic acid, 1249.
Propylphenylthiocarbamide, 477.
Propylpropargylamine, 230.
Propylpyrroline, [1-], 66, 908.
Propylsulphonic acid, γ-amido-, 1090.
Propylsulphuric acid, γ-amido-, 1090.
Propylthiocarbamide, 476.
—— bromo-, 1090.
Propylthiocarbamidebenzyl cyanide, 1104.
Propylthiocarbamideethyl cyanide, 1104.
Propylthiocarbamidemethyl cyanide, 1104.
Propylthiocarbamidepropyl cyanide, 1104.
Propylthiocarbimide, 476.
Propyltrimethylammonium iodide, iodo-, 357.
Propyltriphenylpyrrolone, crystallography of, Trans., 788.
Propylxylenes, 1249.
Proteïd-hydrolyst, Trans., 531.
Proteïds, a cyanogen reaction of, 1032.
—— artificial digestion of, 275.
—— in urine, 1174.
—— heat coagulation of certain, 272.
—— of liver and kidney cells, 1014.
—— of various grasses, composition and digestibility of, 657.
Proteïnchrome, 804.
Proteïnchromogen, 804.
Protoplasm, living vegetable, 283.
Pseudoazimides, 787.
Pseudobrookite, from Havredal, Norway, 219.
—— from Vesuvius, 712.
Pseudobutylene, brominated derivatives of, geometrical isomerism of, 1218.
Pseudocumyl methyl ketone, 981.
Pseudocumylhydrazine, Trans., 54.
Pseudocumylhydrazinepyruvic acid, Trans., 55.
Pseudocumylsemicarbazide, Trans., 55.
Pseudodihexyloxamide, 474.
Pseudohexyl alcohol, 474.
Pseudohexylamine, 474.
Pseudohexylcarbamide, 474.
Pseudoitaconanilic acid, 368.
—— chloride, 369.
Pseudoitacon-α-naphthalic acid, 369.
Pseudoitaconparatolilic acid, 379.
Pseudoitaconphenylhydrazilic acid, 369.
Pseudomeconine, Trans., 1072.
Pseudomeconinic acid, Trans., 1073.
Pseudomethyltarconic acid, 532.
Pseudophenylazimidonaphthalene, 788.
Pseudopianic acid, constitution of, Trans., 1001.
—— —— fusion of, with potash, Trans., 1067.
—— —— preparation of, Trans., 1064.
—— —— reduction of, Trans., 1072.
—— —— salts of, Trans., 1067.
—— oxime, Trans., 1069.
—— —— action of heat on, Trans., 1070.
Pseudotriphenylmelamine, nature of, 1254.
Psilomelanes, 570.
Ptomaïnes, 1170.
Purpura lapillus, colouring matter of, 1452.
Purree, 504.
Putrefaction of serum albumin, gases evolved in the, 78.
Pyocyanin, 189.
Pyrargyrite from Kajénel, Transylvania, 1070.
Pyrazole, synthesis of, 1009.
Pyrazole, β-, derivatives of, 1439.
Pyrazole-bases, compounds of alloxan with, 645.
Pyrazolebenzoic acid, ortho-, 800.
Pyrazolebenzoic acid, para-, 799.
Pyrazole-4 : 5-dicarboxylic acid, β-, 1439.
Pyrazole-group, 1241.
Pyrene, formula of, Proc., 1890, 103.
Pyridine and other bases, equilibrium between, 1364.
—— β-chloro-, derivatives of, 130.
—— constitution of, 1432.
—— compounds of, with mercury salts, 643.

Pyridine, thermochemistry of, 101, 1363, 1368.
Pyridine-bases, betaïnes of, 1431.
—— —— compounds of, with acids of the acetic series, 1156.
—— —— estimation of, in gas-liquor, 1349.
Pyridinebetaïne, 1431.
Pyridinecarboxylic acid, bromo-, 177.
Pyridine-derivatives, conversion of pentamethylene-derivatives into, 129.
—— —— from anilidopyrotartaric acid, 642.
from propaldehyde and propaldehyde-ammonia, 794, 1002.
Pyridineorthocarboxylic acid, 1157.
Pyridines and their relations to quinoline, isoquinoline, and the alkaloids, 794.
Pyridine-series, synthesis of alcohol acids of the, 520.
Pyridylacrylic acid, 520.
Pyridylglyceric acid, 521.
Pyridyl-*α*-lactic acid, 520.
Pyridyl-*β*-lactic acid, 520.
Pyridyl-*ω*-trichloropropylene, 520.
Pyrimidines, 69.
Pyrites, burnt, estimation of sulphur in, 193.
—— estimation of sulphur in, 413.
Pyrobenzylphosphinic acid, 767.
Pyrobenzylthiophosphinic acid, 767.
Pyrocinchonic acid, relation of, to the dimethylsuccinic acids, 743.
—— anhydride, action of phenylhydrazine on, 1327.
Pyrocinchonylphenylhydrazines, *α*- and *β*-, 1327.
Pyrocoll and its derivatives, molecular weights of, 67.
Pyrogallol, physiological action of, 1019.
Pyrogallolbenzeïn, 899.
Pyrogallolcarbothionylic acid, 163.
Pyroglutamic acid, 642.
Pyrographitic oxides, 448.
Pyromucamide, trichloro-, 601.
Pyromucic acid, chloro-derivatives of, 482.
—— —— dichloro-, 600.
—— —— dichloronitro-, 601.
—— —— dichlorosulpho-, 671.
—— —— supposed isomerides of, 1242.
—— —— trichloro-, 601.
Pyromucic acid, *β*-, identity of, with ordinary pyromucic acid, 1242.
Pyromucic acids, chloro-, 600.
—— —— chlorobromo-, 601.
Pyropapaverinic acid, 180.
Pyrophosphates, double, use of, in electrolytic estimations and separations, 294.
Pyrotartaric acid and benzaldehyde, condensation of, 775.
—— —— and œnanthaldehyde, condensation of, 593.
—— —— and salicylaldehyde, condensation of, 777.
—— —— and valeraldehyde, condensation of, 591.
—— acids, brominated, 1097.
Pyroxene of secondary origin, 1081.
Pyrrolidone, 360.
Pyrrolidone-derivatives, preparation and properties of, 793.
Pyrroline, action of acetone on, 999.
—— action of ethyl and propyl iodides on the potassium derivatives of, 907.
—— conversion of, into its homologues, 1428.
—— conversion of, into tetramethylenediamine, 1242.
—— tetriodo-, molecular weight of, 906.
Pyrrolinecarboxylic acid, *α*-, molecular weight of, 906.
Pyrroline-*α*-carboxylic acids, nitro-, 66.
Pyrroline-derivatives, 263,
- action of hydroxylamine on, 1155.
—— —— - from anilidopyrotartaric acid, 642.
- molecular weight of, 906.
- new method of formation of, 1155.
- tertiary, 1430.
Pyrrolines, action of hydroxylamine on, 264.
—— tertiary, 389.
Pyrroylpyruvic acid, imineanhydride of, 1156.
—— anhydride, action of orthophenylenediamine on, 1243,
Pyrryl methyl ketone, action of ethyl oxalate on, 1156, 1243.
Pyruvic acid, condensation of, with sodium succinate, 1102.
—— —— dichloro- and bromodichloro-, 132.

Q.

Quartz, expansion of, 1372.
—— synthesis of, 112.
Quartzine, 712.
Quassia amara, constituents of, 791.
Quassiin, 792.
Quebrachisulphuric acid, 226.
Quebrachite, 226.
Quebracho, sugar from, 226.
Quercetin derivatives, 64.
Quinaldine, bromo-, 1322.
—— chloro-, 1322.

Quinaldine-3 : 4′-dicarboxylic acid, 1325.
Quinazoline-derivatives, synthesis of, 71.
Quinazolines, 1442.
Quinia morada, constituents of the bark of, 404.
Quinidine ferrocyanide, 1318.
Quinine anhydride, 1166.
—— dextrotropate, 74.
—— estimation of, in quinine tartrate, 672.
—— ferrocyanide, 1318.
—— first synthetically prepared base isomeric with, 523.
Quinoidine, oxidation of, 179.
Quinol, chlorodiimido-, 242.
—— chloroparadiacetamido-, 243.
—— chloroparadiamido-, 243.
—— diethyl ether, diamido-, 967.
—— ethylxanthate, thio-, 603.
—— metadichloro-, 242.
—— physiological action of, 1019.
—— thio-, 603.
Quinolglycuronic acid, 1286.
Quinoline, action of, on copper sulphate, 796.
—— 2-bromo-, derivatives of, 173.
—— 2′-bromo-, 521.
—— 4-bromo-, derivatives of, 173.
—— 4′-bromo-, sulphonic acids of, 266.
—— bromo-, La Coste's, constitution of, 173.
—— bromo-derivatives of, 1320.
—— 1 : 2-dibromo-, 173.
—— 1 : 3-dibromo-, and its derivatives, 172.
—— 1 : 4-dibromo-, and its derivatives, 172.
—— 1 : 4′-dibromo-, and its derivatives, 1320.
—— 2 : 3-dibromo-, and its derivatives, 172.
—— 2 : 4-dibromo-, and its derivatives, 172.
—— 2 : 4′-dibromo-, 174.
—— 3 : 4-dibromo-, and its derivatives, 173.
—— 3 : 4′-dibromo-, and its derivatives, 173.
—— 4 : 4′-dibromo-, derivatives of, 173.
—— double salts of, 643.
—— 4 : 3-nitrobromo-, 267.
—— reduction of, 1302.
—— reduction products of, 1318.
—— ring formation, 1004.
—— tetrabromo-, 1321.
—— tribromo-, 173, 522.
—— 1 : 4 : 4′-tribromo-, 1321.
—— trichloro-, 523.
Quinoline-derivatives, regularities in the oxidation of, 1324.
Quinolinedicarboxylic acid, [2 : 4-], 176.
Quinolineparamethenylamidoxime and its derivatives, 175.
Quinolineparamethenylbenzenylazoximeparacarboxylic acid, 176.
Quinolineparamethenylcarbonylamidoxime, 175.
Quinolineparamethenylethenylazoxime, 175.
Quinolineparamethenyluramidoxime, 176.
Quinolines, nitro-1′-bromo-, 521.
—— substituted, reduction of, 1302.
—— —— synthesis of, 1142.
Quinolinesulphonamide, 1 : 4-chloro-, 522.
Quinolinesulphonic acid, 1′-bromo-, 521.
—— —— 3 : 1-bromo-, 267.
—— —— 4 : 1-bromo-, 267.
—— —— 4 : 3-bromo-, 267.
—— —— 4′ : 2-bromo-, 266.
—— —— 4′ : 4-bromo-, 266.
—— —— 1 : 4-chloro-, 523.
—— acids, bromo-, 265.
—— bromide, bromo-, 522.
—— chloride, 1 : 4-chloro-, 522.
Quinolinic acid, bromo-, 177.
Quinoltetracarboxylic acid, pyrazolone derivative of, 984.
—— anhydride, 984.
Quinolyldiphenylcarbamide, *a*-, 501.
Quinone, chlorobromonitro-, 1108.
—— chloroparadiacetamido-, 243.
—— constitution of, 1270.
—— dibromide, 1272.
—— Étard's nitro-, probable non-existence of, Trans., 255.
—— halogen derivatives of, Proc., 1890, 32.
—— isomeric changes in the halogen derivatives of, Proc., 1890, 32.
—— metadibromo-, 165.
—— metadichloro-, derivatives of, 241.
—— tetrabromide, 1272.
—— tetrachloro-, 892.
Quinonediorthonitrotoluidide, 1446.
Quinonehomofluorindine, 1445.
Quinoneimides, 736, 1265.
Quinoneorthodinitranilide, 1445.
Quinoneorthonitrotoluidide, 1446.
Quinoneoximes, action of chlorine on, 1146.
Quinoneparamethylphenazine, 1446.
Quinonephenotolazine, 1446.
Quinones, action of, on orthodiamines, orthonitraniline, and nitroparatoluidine, 1445
—— amido-, 736, 1265.
—— halogen substituted, action of alkalis and ammonia on, 136.
Quinonetolazine, 1446.

Quinoxalines from toluylenediamine and bromacetophenone, constitution of, 524.

R.

Racemic acid, formation of, by the oxidation of unsaturated acids, 1274.
Racemoinosite, 471.
Raffinose, 21, 356.
—— and saccharose, separation of, 732.
—— compounds of, with bases, 580.
—— estimation of, in raw sugar, 301.
—— fermentation of, with beer yeast, 22.
—— formation of, 226.
—— formation of lactic acid, 582.
—— heats of combustion and formation of, 1360.
—— inverted, behaviour of, with phenylhydrazine, 581.
—— not formed from cane-sugar, 582.
—— osazone of, 581.
—— separation of, from molasses, 732.
Raoult's law, behaviour of colloïd substances with respect to, 105.
—— method, determination of molecular weights by, Trans., 804.
Reaction, influence of glass surfaces on the velocity of, 1208.
Reagents, concentration of, 412.
Reddingite from Branchville, 1072.
Refraction, atomic, of the elements, 313.
—— equivalent of phosphorus oxide, Trans., 564.
—— molecular, 1.
—— —— determination of, of salts in their solutions, 1033.
—— —— of nitrates, 1201.
—— —— of the halogen salts of lithium, sodium, and potassium, 549.
—— of allylbenzene- and propenylbenzene-derivatives, 748.
Refractive energy, molecular, and dispersive power of aromatic compounds with saturated lateral chains, relation between, 1201.
—— indices of gases, 201.
—— —— of normal salt solutions, 549.
—— —— of saline solutions, 673.
—— —— of salt solutions, 202.
—— power of salts in solution, 1033.
—— —— of solutions of simple and double salts, 433.
Rennet-ferment, action of, 1175.
Rennin, action of, 1175.
Resazurin, 156.
Resin, distillation of, in a vacuum, 1154.
Resins, analysis of, 1032.
Resistance, internal, of batteries, measurement of, 315.
—— of electrolytic cells, 317.
Reso-orceïn, 1407.
Resorcinol, action of, on egg albumin, 804.
—— brownish-red dye from, 370.
—— chlorodiamido-stannochloride, 241.
—— chlorodinitro-, 241.
—— dicamphoride, 1427.
—— diethyl ether, α- and β-bromo-, 1404.
—— —— —— preparation of, 1404.
—— monocamphoride, 1427.
—— physiological action of, 1019.
—— symmetrical, dinitro-derivatives of, 241.
Resorcinolcarbothionylic acid, 163.
Resorcinol-dyes, 762.
—— —— Weselsky's, 156.
Resorcinolglycuronic acid, 1286.
Resorufamine, 764.
Resorufin, 156.
Respiration, human, 914.
—— in the horse during rest and work, 392, 1170.
—— of entozoic worms, 274.
—— of plants, 190.
Rest, respiration in the horse during, 392, 1170.
Retene perhydride, 385.
Rhamnetin, glucoside of, 64.
Rhamnodiazine, 355.
Rhamnosecarboxylic acid phenylhydrazide, 154.
Rhamnosediphenylhydrazine, 1260.
Rhamnus frangula, frangulin from, Trans., 38.
Rhodium bases, constitution of, 1213.
—— double salts of, 1383.
—— nitrites, 1382.
Rhodotilite from Sweden, 459.
Rice-straw, digestibility of, 546.
Ricin, 535.
Rings, six-membered, theory of, 1299.
Rock-forming minerals, artificial production of, 718.
Rocks, disintegration of, 1183.
—— eruptive, of the Rhone, 115.
—— used in the manufacture of Chinese porcelain, 461.
Rock-salt, Roumanian, 217.
Roemerite, 454.
Root excretions and their influence on organic matter, 656.
Rosaginin, 1316.
Rosamines, 157.
Rosenbuschite, 1079.
Rosindone, 909.
Rosinduline, 908.

Rotatory power of carbon compounds, sign and variations of, and their chemical constitution, 722.
—— —— of matezite and matezodambose, 471.
Rubidium carbonate, reduction of, by magnesium, 332.
—— combining energy of, 108.
—— heat of combustion of, 679.
Rubrite, 456.
Rum, analyses of, 1195.
Ruthenium potassium nitrites, 17.
Rye meal and bran, detection of, in wheat meal and bran, 302.

S.

Saccharic acid, optical isomerides of, 1389.
Saccharic acid, i-, 1392.
Saccharic acid, l-, 1392.
Saccharic lactone, acid from, 599.
"Saccharin," analysis of, 94.
—— effect of, on the digestion of albuminoïds, 1450.
Saccharinic acid phenylhydrazide, 154.
Saccharomyces ellipsoideus, preparation of, 1179.
—— *exiguus*, 951.
Saccharose, separation of raffinose from, 732.
Saccharoses, benzoyl-derivatives of, 578.
Safrole, 965.
—— bromine derivatives from, 638.
—— oxidation of, 136.
Salicenylamidoxime and its derivatives, 142.
Salicenylbenzenylazoxime, 143.
Salicenylethenylazoxime, 143.
Salicenylethylamidoxime, 144.
Salicenylphenyluramidoxime, 144.
Salicenylpropenylazoxime-ω-carboxylic acid, 146.
Salicenyluramidoxime, 144.
Salicylaldehyde and ammonia, action of, on diacetyl, TRANS., 10.
—— and pyrotartaric acid, condensation of, 777.
—— diphenylhydrazone, 1260.
—— reaction of, with albumin, 1350.
Salicylamide, dibromo-, 141.
—— reduction of, TRANS., 957.
Salicylamine, 1411.
Salicylbenzidine, 1298.
Salicylic acid, action of nitrogen iodide on, 1402.
—— —— action of phosphorus trichloride on, 53.
—— —— amido-, action of aniline on, 138.
—— —— commercial, impurities in, 88.
Salicylic acid, detection of, in wine, 1475.
—— —— dichloro-, 1418.
—— —— nitrogen derivatives of, 141.
—— camphoride, 1428.
Salicylometaphenylenediamine, 139.
Salicylometatoluylenediamine, 139.
Salicylonitrile, preparation of, 141, 146.
—— polymerides of, 146.
Salicylophosphorus chloride, 53.
Salicylothiamide, 141.
—— dibromo-, 142.
Saline mixtures, solubility of, 442.
Saliva, detection of nitrous acid in, 278.
Salivary secretion, influence of nicotine and atropine on, 397.
Salt-deposits, Stassfurt, occurrence of hydrogen sulphide and sulphur in, 336.
Salts, change of volume on dissolving, in water, 844.
—— containing water, dissociation of, and the constitution of the combined water, 206.
—— dissolved, voltaic energy of, 317.
—— estimation of water and carbonic acid in, 417.
—— formation of, in alcoholic solution, 553.
—— fused and solid, electrical conductivity of, 1037.
—— influence of, on clotting, 1176.
—— inorganic, influence of, on the development of frogs' spawn, 393.
—— —— residual affinity of, 444.
—— in solution, refractive powers of, 1033.
—— metallic, action of sulphur on, 9.
—— —— electromotive force of, 843.
—— reciprocal influence on the solubility of, 3.
—— simple and double, refractive power of, 433.
—— stability of, alone and in presence of water, 1361.
—— substitution of, in mixed solutions, 443.
—— sudden changes in the solubility of, caused by the formation of two layers in the liquid, 4.
Salt-solutions, dilatation of, 318.
—— —— refractive indices of, 202, 549.
—— —— supersaturated, sp. gr., sp. heat, and heat of dissolution of, 1042.
Samarium oxides, new fluorescences of, 435.
Sandmeyer's reaction, improvement in, 1149.
Santoninoxime and its derivatives, 902.
Santoninphenylhydrazone, 904.

Saponification, method for, 1474.
Sapphirine from Fiskernas, Greenland, 19.
Sarkinite, crystals of, 715.
Sassafras oil, the phenol contained in, 1111.
Scatolacetic acid, 78.
Scatole in the vegetable kingdom, 191.
Scheelite, method for the analysis of, 420.
Scopolia atropoïdes, constituents of, 658.
Scopolia carnicola, chemical constituents of, 402.
Scutellarin, 64.
Sealing tubes under pressure, 941.
Sea-mud of the alluvia of the Zuiderzee, 822.
Sea-water, solubility of some substances in, 719.
Secretion of amidic substances, effect of feeding on the, 278.
Seed, resting and germinating, genesis of two varieties of diastase in the, Trans., 505.
Seeds of the corn cockle, poison of, 1458.
—— sugar-yielding, insoluble carbohydrates in, 544.
—— utilisation and transformations of alkaloïds during the germination of, 543.
Selenic acid, preparation, properties, and reactions of, 688.
Selenious acid, physiological action of, 542.
Selenium and oxygen derivatives of benzene, 34.
—— chlorides, vapour densities of, 558.
Selenocarbamides, ψ-, 880.
Selenocyano-derivatives, 949.
Semithiocarbazides, Trans., 257.
—— relations between the solubilities and melting points of, Trans., 264.
Senegin, from *Polygala senega*, 262.
Seneginin, 262.
Serpentine from Finland, 715.
—— from Montville, New Jersey, 716.
Sesame oil, testing, 90.
Sewage, estimation of ammonia in, 1024.
Silage, preparation of, 546.
Silica, a new form of, 569.
—— action of magnesium on, 1374.
—— and its compounds, behaviour of, in fused microcosmic salt, 825.
—— estimation of, 194.
—— estimation of, in silicates, 1026.
—— expansion of, 1371.
—— influence of, on the decomposition of potassium chlorate, Trans., 276.
—— new forms of crystallised, 712.
Silicates, analysis of, 1027.
Silicates, behaviour of, when fused with phosphates, 84.
—— containing tin and titanium, analysis of, 665.
—— formation of, 113.
—— formulæ of, 219.
Silicic acid as a culture medium for organisms, 1338.
—— —— estimation of, in soils, 833.
—— —— molecular weight of, 1216.
—— acids occurring in minerals, 342.
Silicon bromide, compounds of, with ammonia and hydrogen phosphide, 559.
—— chloride, combination of ammonia and hydrogen phosphide with, 559.
—— —— preparation of, 108.
—— compounds of, with magnesium, 1373.
—— fluoride, combination of hydrogen phosphide with, 448.
—— influence of, on steel, 567.
—— nitride, 108.
—— preparation of, 108.
—— sesquichloride, combination of ammonia and hydrogen phosphide with, 690.
Silk, thermochemical properties of, 553.
Sillimanite, production of, 1074.
Silver, allotropic forms of, 210, 334.
—— and the alkali metals, isomorphism of the chlorates of, 1208.
—— antimonate, 216.
—— atomic weight, &c., of, 561.
—— benzamide, 491.
—— carbonate and oxide, action of magnesium on, 333.
—— carbonylferrocyanide, 117.
—— chloride, action of light on, 213.
—— chloride, darkened, not an oxychloride, 335.
—— chromiodate, 1378.
—— cyanide, action of cupric salts on, 464.
—— dibenzamide, 1269.
—— effect of, on the freezing point of tin, Trans., 377.
—— electrolytic estimation of, 294, 1029.
—— electrolytic separation of, from arsenic, molybdenum, and tungsten, 1029.
—— electrolytic separation of, from copper, zinc, nickel, and cobalt, 664.
—— formanilide, 1414.
—— haloïd salts of, effect of the spectrum on, 933.
—— iodide, fused and solid, transfer of ions in, 317.
—— malonate, 1397.
—— metallic, detection of, in presence of lead, 826.

Silver metanitrobenzamide, 973.
—— nitrate, isomorphism of, with the alkali nitrates, 328.
—— oxide, influence of, on the decomposition of potassium chlorate, Trans., 279.
—— salts, action of sodium thiosulphate on, 694.
—— silicate, 849.
—— sub-fluoride, 1055.
Silver-bismuth-glance, artificial, 710.
Silver-carbamide, action of iodine on, 974.
Slags, estimation of phosphoric acid in, 292.
Soap, estimation of fatty acids in, 1475.
—— lyes, estimation of glycerol in, 423.
—— solution, standard, preparation of, 198.
—— test, Clarke's, 421.
Soda, commercial caustic, volumetric estimation of sodium carbonate and hydroxide in, 293.
—— natural, or urao, 340.
—— or potash and carbon, use of, in analysis, 1027.
Sodalite, formation of, 1080.
Sodammonium, 210, 450, 560, 679.
—— heat of formation of, 319.
Sodionitrethyl alcohol, 858.
Sodiophenylmercaptide, behaviour of, with isobutylene bromide, 962.
Sodium alum, 1059.
—— and potassium chlorides, simultaneous solubility of, 103.
—— —— —— solubility of mixed, 442.
—— arsenate, action of, on sesquioxides, 1377.
—— benzenesulphoncyanamide, 501.
—— benzylthiosulphate, 1419.
—— borneol camphorate, 790.
—— cadmium thiosulphate, 1057.
—— carbonate and hydroxide, volumetric estimation of, in caustic soda, 293.
—— —— crystalline, and chlorine, direct preparation of, from sodium chloride, 10.
—— —— reduction of, by magnesium, 332.
—— carbonylferrocyanide, 117.
—— chloride, molecular refraction of, in water, 1033.
—— —— violet flame produced by, in a coal fire, 1202.
—— combination of ammonia with, 209.
—— dibromoparaxylenesulphonate, Trans., 978.
—— effect of, on the freezing point of tin, Trans., 380.
Sodium erythroxide, heat of formation of, 935.
—— —— preparation of, 935.
—— hydroxide, compound of, with isobutyl alcohol, 1222.
—— hydroxymethylenesulphonate, 1092.
—— iron sulphide, 215.
—— lead chromates, 1065.
—— molecular refraction of the halogen salts of, 540.
—— nitrate and ammonium sulphate, comparative manurial value of, 287.
—— nitroprusside, reactions of, 198.
—— orthoxythiovanadate, 1381.
—— orthoxytrithiovanadate, 1381.
—— perchlorate, properties of, 333.
—— phosphate, influence of, on the excretion of uric acid, 397.
—— —— presence of magnesium in, 664.
—— phosphites, 438.
—— pyrophosphite, 438.
—— rhodium nitrite, 1382.
—— —— sulphite, 1383.
—— sesquicarbonate, 340.
—— succinate, heat of formation of, 320.
—— sulphate, analysis of, 194.
—— —— from Arizona, 572.
—— sulphide, commercial, technical analysis of, 84.
—— ac.-tetrahydro-β-naphthylcarbonate, 507.
—— ac.-tetrahydro-β-naphthylxanthate, 508.
—— thiosulphate, action of, on metallic salts, 12.
—— —— action of, on silver salts, 694.
—— —— behaviour of, towards acids and bases, 10.
—— triiodate, 107.
—— urate, thermochemistry of, 1041.
—— xylenesulphonate (para), Trans., 978.
Soil, arable, causes of the exhaustion of, by cropping without manures, 406.
—— influence of the composition of, on the physical properties of plants, 81.
—— loss and gain of nitrogen by, 1023.
—— nitrogen, influence of gypsum and clay on the conservation of, 545.
Soils, arable, formation of, 1183.
—— atmosphere in, 81.
—— composition of, 1339.
—— cultivated but unmanured, exhaustion of, 1459.
—— decomposition of organic manures in, 1183.
—— estimation of potassium and humus in, 668.

Soils, estimation of water, humus, sulphur, &c., in, 832.
—— moorland and peat, examination of, 192.
—— of Deli, Malang, and Rembang, 823.
—— vegetable, absorption of ammonia from the air by, 821, 822.
Sobrerol, Proc., 1890, 100.
Sobrerone, Proc., 1890, 100.
Soja bean, white, analysis of, 192.
Solaneïne, 75.
Solanidine, 75.
—— in potato-shoots, 1182.
Solanine, 75.
—— reaction of, 310.
Solanum tuberosum, bases contained in the young shoots of, 75.
Solubility and heat of fusion, relation between, 686.
—— influence of one salt on the, of another, 3.
—— of salts, sudden changes in the, caused by the formation of two layers in the liquid, 4.
—— simultaneous, of sodium and potassium chlorides, 103.
Solution, dissociation of substances in, 325.
—— molecular weight of metals in, Trans., 376, 656.
—— of carbonates in acids, rate of, 843.
—— theory of, 3.
Solution-compounds, 941.
Solutions, aqueous, dispersive power of, 673.
—— —— vapour pressure of, 323.
—— colloïdal, freezing of, 685.
—— constitution of, 1044.
—— determination of the vapour pressures of, 1364.
—— exceptions to the gaseous laws in, 442.
—— freshly prepared, change of electrical conductivity in, 204.
—— homogeneous, equilibrium in, when unequally heated, 444.
—— in acetic acid, vapour pressures of, 554.
—— isomeric, molecular constitution of, 207.
—— law of the freezing points of, Proc., 1890, 9.
—— mixed, electrolysis of, 317.
—— mixed, substitution of salts in, 443.
—— nature of, 845, Trans., 64.
—— nature of, as elucidated by the freezing points of sulphuric acid solutions, Trans., 331.
—— rise of, in capillary tubes, 684.
—— saline, dilatation of, 318.
Solutions, salt, refractive indices of, 202.
—— solid, 1044.
—— supersaturated, 333.
—— the question of free ions in, 325.
—— theory of, 845.
Solvent, lowering of the freezing point of, 846.
Sorbin, hydrogenation of, 1389.
Sorbite, 21.
—— action of cuprammonium sulphate on, 21.
—— benzoic acetals of, 730.
—— conversion of glucose into, 1389.
—— oxidation of, 1389.
Sorghum-cane, organic acids in, 819.
Spangolite, 1073.
Sparteïne ferrocyanide, 1318.
Specific gravity apparatus, 206.
—— —— of ammonia solutions, 107.
—— —— of supersaturated salt solutions, 1042.
—— heat of supersaturated salt solutions, 1042.
—— heats, experimental determination of the ratio of, in superheated steam, 205.
—— inductive capacity of water, 203.
—— volume of aqueous vapour, 207.
—— —— of phosphorus, Trans., 562.
—— volumes of camphor and borneol, 169.
—— —— of some ethereal salts of the oxalic acid series, 102.
Spectra, absorption-, of oxygen, 675.
—— line-, of the elements, structure of, 671.
—— of gases at low temperatures, 313.
Spectrum, absorption-, of ζ-invertan, Trans., 912.
—— —— of nitrosyl chloride, 97.
—— effect of, on the haloïd salts of silver, 933.
—— emission-, of ammonia, 97.
—— of fluorine, 329.
Sphærolite tachylite from the Ussuri district, 461.
Spirituous liquors, examination and valuation of, 1194.
Spleen, function of, 184.
—— of young animals, quantity of iron in, 185.
Splenic vein, is free hæmoglobin present in the blood plasma of the ?, 1016.
Stachyose, 1089.
Stachys tuberifera, carbohydrate from, 1088.
—— —— nitrogenous constituents of the tubercles of, 1183.
Stannic chloride, electrical and chemical properties of, 1065.
—— —— freezing point of, 331.

Stannous chloride, action of sulphur on, 9.
Starch, digestion of, 537.
—— estimation of, in fodders, 1197.
—— estimation of, in grain, 928.
—— formation of, in the green plant, from certain organic substances, 1021.
—— growth of excised embryos on, Trans., 489.
—— in the endosperm, functions of, Trans., 478.
—— reserve, changes of, in the growing embryo, Trans., 513.
—— —— form in which, enters the embryo, Trans., 513.
—— ungelatinised, action of diastase of secretion on, Trans., 510.
Starches, saccharification of, by acids, 1089.
Steam, superheated, experimental determination of the ratio of the specific heats in, 205.
Stearic acid, bromo-, 1396.
—— —— chloro- and dichloro-, 1396.
Stearin, beef, testing lard for, 428.
Stearone oxime, Trans., 539.
—— —— preparation of, Trans., 537.
Steel, aluminium, analysis of, 1471.
—— estimation of chromium and copper in, 85.
—— estimation of free and combined carbon in, 1027.
—— estimation of minute quantities of aluminium in, 548.
—— estimation of sulphur in, 1463, 1464.
—— influence of foreign metals on the properties of, 566.
—— nature of, 215.
—— relation between the atomic volume of foreign metals and their influence on, 567.
Stereochemical isomerism of asymmetrical monoximes, 1263.
—— research, results and aims of, 719.
—— studies, 602.
—— —— in the piperazine group, 1331.
Stereochemistry of ethane-derivatives, 1083.
—— of nitrogen, 1330.
—— of nitrogen compounds, 575, 951, 970.
Stibiatil, 1076.
Stilbazole, metamido-*α*-, 1438.
—— metanitro-*α*-, and its reduction products, 1437.
Stilbazolene, metamido-*α*-, 1438.
Stilbene, derivatives of, 783.
—— formation of, 978.
Stilbene-group, isomerism in the, 1299.
Straw, composition of, 1459.
Straw, method for the analysis of, 1460.
Strawberries, analyses of, 659.
Straw-gum, 1460.
Strontia raffinose, 580.
Strontium and barium, separation of, 826, 924.
—— cadmium thiosulphates, 1058.
—— chlorate, and the velocity of its decomposition by heat, 696.
—— oxide, action of magnesium oxide on, 452.
—— —— crystalline, 850.
—— plumbate, 561.
—— silicofluoride, solubility of, 925.
—— thiosulphate, 330.
Strophanthin, properties of, 262.
Strophanthus hispidus, 262.
Strychnine, 1328, 1447.
—— amidobromo-, 1329.
—— dihydroxide, 1448.
—— ferrocyanide, 1318.
—— hydroxide, 1448.
—— methiodide, *α*-bromo-, 1329.
—— —— nitrobromo-, 1329.
—— methohydroxide, nitrobromo-, 1329.
Stylophoron diphyllum, alkaloïds of the root of, 649.
Suberonyl alcohol, 728.
Suberonylene, 728.
Sublimates, saline, at Vesuvius, 570.
Substitution-phenomena, dependence of, on the atomic or molecular weights of certain atoms or groups, 484.
Succinenediamidoxime, 125.
Succinenediazoximedibenzenyl, 125.
Succinenediuramidoxime, 125.
Succineneimidodioxime, 125.
Succinic acid and acetaldehyde, condensation of, 584.
—— —— and anisaldehyde, condensation of, 770.
—— —— and butaldehyde, condensation of, 588.
—— —— and chloral, condensation of, 586.
—— —— and isobutaldehyde, condensation of, 589.
—— —— and propaldehyde, condensation of, 587.
—— —— and valeraldehyde, condensation of, 590.
—— —— heat of dissolution of, 320.
—— —— series, theory of anhydride formation in, 741.
—— acids, substituted, 237.
—— —— anhydride-formation and intramolecular change of, substituted, 744.
—— —— chloro- and bromo-, 363.
—— —— mono-, di-, and tri-substituted, preparation of, 742.

Succinic acids, substituted, electrical conductivity of, 1038.
—— chloride, constitution of, 236.
—— series, anhydride- formation in acids of the, 479.
Succinimide, thermochemistry of, 1360.
Succinylbenzimide, 69.
Succinylethylenephenylhydrazine, 250.
Sugar, absorption of, from the small intestine, 276.
—— brain-, identity of, with galactose, 121, Trans., 57.
cane-, action of invertase on, Trans., 843.
formation of, in etiolated plant shoots, 282.
formation of lactic acid from, 582.
influence of temperature on the specific rotation of, 579.
—— —— transformation of, into dextrose, 21.
—— changes in, in the muscle during work, 185.
—— detection of, in urine, 427.
—— estimation of the mineral matter in, 670.
—— formation of paralactic acid in the fermentation of, 78.
—— from fucus, 1105.
—— from the Quebracho, 226.
—— in the blood and in the chyle, 276.
—— in urine, estimation of, by fermentation, 836.
—— in urine, substances likely to be mistaken for, 279.
—— inversion of, 1085.
invert-, alcoholic fermentation of, 950.
estimation of, 836.
—— polariscopic estimation of, in sweet wines, 426.
—— presence in chyle of a ferment which destroys, 810.
—— raw, estimation of raffinose in, 301.
—— *rôle* of, and development of, during the growth of the beetroot, 1020.
—— value of the phenylhydrazine test for, 835.
—— with an aromatic nucleus, 244.
Sugar-group, acids of the, 1398.
—— —— general account of recent research on, 1223.
—— —— reduction of acids of the, 597.
—— —— syntheses in the, 1223.
Sugars, analysis of, 301.
—— and furfuran-derivatives, relation between, 33.
—— behaviour of hydroxides of calcium and the alkalis with, 579.
Sugars, estimation of ash in, 1472.
—— estimation of, with copper potassium carbonate solution, 1031.
—— heats of combustion and formation of, 1360.
—— multirotation of, 1084.
—— richer in carbon from d.-mannose, 1230.
—— synthesised, from formaldehyde, cryoscopic behaviour of, 465.
Sugar-yielding insoluble carbohydrates in seeds, 544.
Sulphanilic acid, action of nascent nitrous acid on, 39.
—— —— dibromo-, 165.
Sulphates, alkaline, reduction of, by hydrogen and by carbon, 1053.
Sulphides, alkaline, detection of, 291.
—— aromatic, preparation of, 1292.
—— crystalline, from the Mechernich lead works, 338.
—— double, of the alkali metals and the heavy metals, synthesis of, 215.
—— metallic, obtained in the wet way, composition of, 1216.
—— mineral, synthesis of, 709.
—— oxidation of, by the electrical current, 1342.
Sulphines, 880.
—— and the different valencies of sulphur, 1234.
—— double cyanides of, 880.
Sulphites, estimation of alkalis in presence of, 1468.
Sulphocinchonic acid, 1435.
Sulphonal, physiological action of, 542.
Sulphonamic acids, aromatic, 1137.
Sulphonation with potassium hydrogen sulphate, 1149.
Sulphoncyanamides, 501.
Sulphonecarboxylic acids, analogy of ketonic acids to, 781.
—— —— reaction of, 781.
Sulphones, decomposition of, 987.
—— derivatives of, 379.
—— preparation of, 780.
Sulphonic acid-group, displacement of the amido-group by, 1137.
Sulphonic-derivatives, action of heat on a mixture of sulphuric acid and, 51.
Sulphophenylazo-ar.-tetrahydro-*α*-naphthol, 509.
Sulphophenylazotetrahydroquinoline, 1302.
Sulphur, action of, on solutions of metallic salts, 9.
—— and carbon, simultaneous estimation of, 290.
—— behaviour of, in the organism, 812.
—— combustion of, at high pressure, 1050.

Sulphur, dissolved, molecular weight of, 447.
—— estimation of, in burnt pyrites, 193.
—— estimation of, in organic sulphides, 1187.
—— estimation of, in iron, 921.
—— estimation of, in iron and steel, 1463, 1464.
—— estimation of, in organic compounds, 289.
—— estimation of, in pyrites, 413.
—— heat of combustion of substances containing, 1361.
—— in carbon compounds, oxidation of, 1462.
—— in coal, estimation and occurrence of, 414.
—— igniting point of, 849.
—— occurrence of, in the Stassfurt salt deposits, 336.
—— rhombic, from hydrogen sulphide, 1371.
—— the different valencies of, 1234.
—— vapour density of, 1365.
Sulphur-methæmoglobin, 1013.
Sulphuric acid, action of, on antimonious oxide, Trans., 541.
—— —— combined, volumetric estimation of, 414.
—— —— compounds of vanadic anhydride with, 336.
—— —— dilute, action of zinc on, Trans., 815.
—— —— estimation of, in soils, 833.
—— —— fuming, estimation of sulphuric anhydride in, 414.
—— —— hydrates of, Trans., 128.
—— —— influence of, on the action of invertase on cane-sugar, Trans., 855.
—— —— isolation of a tetrahydrate of, existing in solution, Proc., 1889, 128.
—— —— monohydrate of, Trans., 130.
—— —— solutions, Trans., 64.
—— —— —— densities of, Trans., 69—86, 139—158.
—— —— —— electrical conductivity of, Trans., 86—88, 158—160.
—— —— —— expansion by heat of, Trans., 114—121, 177—184.
—— —— —— freezing points of, Trans., 331.
—— —— —— heat capacity of, Trans., 88—94, 160—164.
—— —— —— heat of dissolution of, Trans., 94—114, 165—177.
—— —— source of error in the estimation of, 1342.
—— —— test for nitrous compounds in, 922.
Sulphuric acid, tetrahydrate of, Trans., 339.
—— —— volumetric estimation of, 825.
—— anhydride, action of, on antimonious oxide, Trans., 541.
—— —— estimation of, in fuming sulphuric acid, 414.
Sulphurous anhydride and phenylhydrazine, compound of, 617.
—— —— influence of, on the dissolution of zinc in dilute sulphuric acid. Trans., 821.
Supersaturated solutions, 333.
Swimming bladder of fishes, gases in, 183.
Syenite-pegmatite veins of the South Norwegian augite and nepheline syenites, minerals from, 1077.
Syenites, near Glatz, in Lower Silesia, 1076.
Sylvanite from Nagyág, 711.
Symphoricarpus racemosa, calcium oxalate in the leaves of, 191.

T.

Tachylite-sphærolite, from the Ussuri district, 461.
Talc, constitution of, 948.
Tallow, rapid method for the analysis of, 305.
Tanghinin, 171.
Tannin, a new reaction of, 896.
—— action of phenylhydrazine on, 896.
—— estimation of, by means of iodine, 1348.
—— estimation of, by permanganate, 430.
—— from the Slavonian oak, 164.
—— function of, in plants, 819.
—— Gantter's method of estimating, 1477.
—— in barks, colorimetric estimation of, 1348.
—— in Indian and Ceylon teas, 820.
—— oxidation of, 1130.
—— reaction of, 1275.
—— volumetric estimation of, 931.
—— volumetric estimation of, in wines, 431.
Tanning materials, lime in, 312.
Tannins, 164, 257.
—— physiology of, 186.
Tantalum, microscopical test for, 86.
Tapeworms, mercury in, 396.
Taps, vacuum, Trans., 958.
Tartaric acid, anilides and toluidides of, 1112.
—— —— estimation of, in vinegar, 428.
—— —— estimation of, in wine, 427.

Tartaric diorthotoluidide, 1112.
—— diparatoluidide, 1113.
Tartrate solutions, circular polarisation of, 313.
Taurine, heats of combustion and formation of, 1361.
Tautomeric compounds, 983.
experiments to determine the constitution of, 499.
Taxine ethiodide, 650.
—— the alkaloid of the yew tree, 650.
Teas, Indian and Ceylon, tannin in 820.
Tellurium, evidence of the occurrence of a new element in, 434.
Temperature in nerves, 536.
—— influence of, on the exhalation of carbonic anhydride, 1334.
—— influence of, on the magnetism of salts of metals of the iron group, 678.
—— volume and pressure, relation of, in the case of liquids, 321.
Terephthalic acid, reduction products of 1130.
—— —— preparation of, 1130.
Terpene, dextrorotatory, from *Pinus cembra*, 789.
—— from the oil of *Pinus abies*, 789.
Terpenes, 1314.
Tetrabenzoyltriamidophenol, 371.
Tetrabenzylphosphonium iodide, 767.
Tetracetylbrazilein, di- and tri-bromo-, 997.
Tetracetyldiamidoapione, 1295.
Tetracetylparadiamidochloroquinol, 243.
Tetradecylaldoxime, 1234.
Tetradecylamine, 1234.
Tetrahydrobromhydroxyquinoline hydrochloride, 177.
Tetrahydrodiphenylphenanthroline, 139.
Tetrahydro-α-ethoxynaphthalene, ar.-, 509.
Tetrahydromethylfurfuran, 20.
Tetrahydronaphthalene, 1146.
Tetrahydro-α-naphthalene, ar.-amidoazo-, 1305.
Tetrahydro-α-naphthaquinol, ar.-, 1305.
Tetrahydro-α-naphthaquinone, ar.-, 1305.
Tetrahydronaphthathionine, 1300.
Tetrahydronaphthindamine, 1300.
Tetrahydro-α-naphthol, ar.-, 508.
Tetrahydro-β-naphthol, ac.-, 506.
Tetrahydro-β-naphthol, ar.-, 627, 633.
Tetrahydro-β-naphthyl acetate, ac.-, 507.
—— benzoate, ac.-, 507.
—— chloride, ac.-, 507.
—— phenylcarbamate, ac.-, 507.
Tetrahydro-β-naphthylalmines, ac.-, and ar.-, 631.
Tetrahydronaphthylenediamine, ac.-1 : 4-, decomposition of, into its optically active components, 511.
Tetrahydro-1 : 4-naphthylenedichlorodiimide, ar.-, 1300.
Tetrahydrophenylhydroxyketoquinazoline, 70.
Tetrahydrophthalic acid, Δ^1-, 1280.
Tetrahydrophthalic acid, Δ^2-, 1279.
Tetrahydrophthalic acid, Δ^3-, 1281.
Tetrahydrophthalic acid, $\Delta^{4\,\mathrm{cistrans}}$-, 1281.
Tetrahydrophthalic anhydride, Δ^1-, 1280.
Tetrahydrophthalic anhydride, Δ^2-, 1280.
Tetrahydrophthalic anhydride, $\Delta^{4\,\mathrm{cistrans}}$-, 1281.
Tetrahydroquininic acid, 177.
Tetrahydroquinoline, colouring matters from, 1005.
Tetrahydroquinolinedimethylanilinethiosulphonic indamine, 1006.
Tetrahydroterephthalic acid, Δ^1-, oxidation of, 1134.
Tetrahydroterephthalic acid hydriodide, $\Delta^{2\,\mathrm{cistrans}}$-, 1134.
Tetrahydroxyditolyl, 39.
Tetrahydroxyphenyl diethyl ether, 968.
Tetrahydroxyquinone, action of orthophenylenediamidine, on, 1265.
Tetrahydroxystearic acid, 363.
Tetraisobutyl oxalate, 236.
Tetraketohexamethylene, dibromodichloro-, 1271.
—— tetrabromo-, 1272.
—— tetrachloro-, 1271.
Tetraketopiperazines, attempts to prepare, 1161.
Tetramethyl oxalate, 236.
Tetramethylapionole, 36.
—— dinitro-, 1295.
Tetramethylbenzamide, 158.
Tetramethylbenzidine, 138.
Tetramethyldiamidoquinone, preparation of, 757.
Tetramethyldihydropyridine, action of methyl iodide on, 67.
Tetramethyldiphenyline, 167.
Tetramethylenediamine, conversion of pyrroline into, 1242.
Tetramethylethylene, action of chlorine on, 727.
Tetramethylhexaphenyl ether, 959.
Tetramethylphloroglucinol, action of hydrochloric acid on, 1407.
Tetramethylrosamine, 157.
Tetramethylsuccinic acid, 132, 479.
—— anhydride, 479.
Tetramethylstrychnine dihydroxide, 1448.
Tetramethyltricarballylic acid, 747.

Tetraminechromic salts, chloro-, 1213.
Tetraminecobalt salts, chloro-, 1214.
Tetramyl oxalate, 236.
Tetranaphthylcarbamide, β-, 994, 1311.
Tetranilidonaphthalene, 911.
Tetraparatolylamidodimethyleneorthophenylenediamine, 247.
Tetraphenyldiamidodimethylenediphenylenediamine, 246.
Tetraphenyldihydro-orthodiazine, Trans., 647.
—— action of excess of phenylhydrazine on, Trans., 649.
Tetraphenylenefurfuran, Proc., 1890, 32.
Tetraphenylpyrroline, ααβ-N-, Trans., 646.
Tetraphenyltetracarbazone, 1268.
Tetraphenylthiophen, 1246.
Tetraphenyluvinone, Trans., 956.
Tetrapropyl oxalate, 236.
Tetrethoxybenzene, 968.
Tetrethyl oxalate, 236.
Tetrethylbenzidinephthalic acid, 1298.
Tetrethylphloroglucinols, bromo-, 243.
Tetrethylrosamine, 157.
Thallium ammonium tartrate, circular polarisation of, 314.
—— antimony tartrate, circular polarisation of, 314.
—— effect of, on the freezing point of tin, Trans., 379.
—— electrolytic estimation of, 295.
—— hydrogen tartrate, circular polarisation of, 313.
—— lithium tartrate, circular polarisation of, 313.
—— oxide, crystalline hydrated, 109.
—— oxides, action of magnesium on, 694.
—— potassium tartrate, circular polarisation of, 314.
—— salts, physiological action of, 1452.
—— sodium tartrate, circular polarisation of, 313.
—— —— thiosulphate, 12.
—— tartrate, circular polarisation of, 313.
Thenardite, 456.
Thermal behaviour of cupric chloride solutions, 1206.
—— expansion of phosphorous oxide, Trans., 560.
Thermochemical properties of silk, 553.
—— value of the hydroxyl and carboxyl groups in the aromatic series, influence of certain groups on, 439.
Thermochemistry of allotropic forms of arsenic, 679.
—— of hydroxylamine, 934.
—— of methyl alcohol and solid methyl salts, 100.
Thermochemistry of nicotine, 101.
—— of some organic acids, 99.
—— of wool and cotton, 939.
—— use of aluminium amalgam in, 110.
—— See also Heat.
Thermoelectric forces at the surface of contact of a metal and a fused salt, 551.
Thermometer, platinum, Trans., 657.
Thermometers, mercurial, determination of fixed points on, Trans., 656.
Thermometric readings, correction of, 205.
Thioarsenates, 1053.
Thiocarbamide, action of allyl bromide on, Trans., 299.
—— action of benzyl chloride on, Trans., 284.
—— conversion of, into carbamide, 1399.
Thiocarbamides, action of hydroxylamine and its derivatives on, 1126.
—— aromatic, derivatives of, 526.
—— —— pseudo-, 159.
—— chemistry of, Trans., 283.
Thiocarbamidocresol, 248.
Thiocarbamidocumenol, 249.
Thiocarbamidonaphthol, 248.
Thiocarbamido-α-naphthol, 249.
Thiocarbamidophenanthrol, 249.
Thiocarbanilide, constitution of, 500.
Thiocarbanilotoluyleneoxamethane, 1125.
Thiocarbanilotoluyleneurethane, 1125.
Thiocyanamidocinnamic acid, 1123.
—— —— meta-, 1124.
Thiocyanates, alkaline, detection and estimation of chlorine in, 663.
—— formation of, from amido-compounds, 749.
—— gravimetric estimation of, 424.
Thiocyanic acid, coloration of organic substances by, 726.
—— —— new reaction of, 424.
Thiocyanobutyronitrile, γ-, 1221.
Thiocyano-derivatives, 949.
Thiocyanopropylphthalimide, γ-, 472, 1090.
Thionylparatolylhydrazone, 617.
Thionylphenylhydrazone, 617.
Thiophen, heats of combustion and formation of, 1361.
—— preparation of, 1400.
Thiophen-derivatives, conversion of pentamethylene-derivatives into, 129.
Thiosulphates, 210, 330, 564, 1057.
Thiosulphuric acid, detection of, in urine, 812.
Thiovanadates, 1381.
Thioxanthone, preparation of, 1292.

Thoria minerals from Llano Co., Texas, 457.
Thorium and uranium, new case of isomorphism of, 15.
—— sulphate, 15.
—— —— and its hydrates, solution-equilibrium of, 686.
Thoro-gummite, 458.
Thrombogenic enzymes, TRANS., 531.
Thrombogens, TRANS., 531.
Thymol, bromo-, derivatives of, 366.
—— bromonitro-, and dinitro-, constitution of, 753.
—— derivatives of, 883.
—— dinitro-, 602.
—— ethyl ether, amidobromo-, 883.
—— —— —— orthobromo-, 883.
—— nitrobromo-, 366.
—— nitro-derivatives of, 602.
—— nitroso-, action of hydroxylamine on, 1403.
—— paramido-orthobromo-, 602.
—— paranitro-orthobromo-, 602.
Thymolcinnamic acid, 892.
Thymolglycuronic acid, 1286.
Thymoquinone, chlorhydroxy-, constitution of, 884.
Thymoquinones, bromo-, 367.
—— halogen, isomerism of, 367.
—— isomeric chloro- and bromo-, constitution of, 753.
Thymyl phenylcarbamate, 760.
Tiglamide, chloro-, 958.
Tiglic acid, derivatives of, 862.
Tin and titanium, separation of, 1029.
—— —— separation and estimation of, 666.
—— copper and lead, alloy of, 335.
—— detection of, in minerals, 830.
—— double phosphates, 1379.
—— effect of various metals on the freezing point of, TRANS., 376.
—— electrolytic estimation of, 294.
—— estimation of lead in, 665.
—— eutectic alloys, TRANS., 386.
—— lead and zinc, alloys of, 336.
—— mineral in process of formation, 1082.
—— ore, analysis of, 1027.
—— oxide, influence of, on the decomposition of potassium chlorate, TRANS., 276.
—— precipitation of, from acid solutions by metallic iron, 853.
—— tetraphenyl, 166.
Tintometer, 1461.
Titanic anhydride, crystallisation of, 1071.
Titanium and tin, separation and estimation of, 666.
—— —— separation of, 1029.
Titanium dioxide, action of magnesium and hydrogen on, 1375.
reduction of, by magnesium, 1374.
chloride, action of, on metals, 1066.
—— double phosphates, 1379.
Tobacco, causes of the fertility of the forest land of Deli for, 1340.
—— estimation of nicotine in, 430.
—— influence of the ash constituents on the combustibility of, 1458.
—— leaves, composition of the ash of, 1338.
Tolane, chlorine compounds of, 899.
—— dichlorides, 783.
Tolidinedisulphonic acid, ortho-, 60.
Tolidinesulphone, 60.
Tolidinesulphonic acid, ortho-, 60.
Toluamide, ω-chloropara-, 239.
Toluanilide, para-, 759.
Tolubenzylacetamide, para-, 969.
Tolubenzylamine, ortho- and para-, derivatives of, 968.
Tolubenzylcarbamide, para-, 969.
Toluene, action of lead oxide on, 962.
—— nitro-derivatives of metabromo-, 485.
—— parachloro- and parabromo-, melting point of, 3.
—— physical constants of halogen derivatives of, 2.
Tolueneazo-β-naphthylphenylamine, 992.
Toluenecyanosulphochloride, 382.
Toluenecyanosulphonic acid, 382.
Tolueneoxamethane, 1124.
Toluenesulphonic acid, diamido-, 502.
Toluic acid, ω-chloropara-, 239.
—— acids, isomeric paranitro-, 52.
Toluidine malate, ortho-, 1163.
Toluidine, para-, action of bromine on, in presence of sulphuric acid, 137.
—— —— estimation of, 839.
—— —— oxalate, 137.
Toluidines, ortho- and para-, action of nascent nitrous acid on, 38.
—— —— —— chlorination of, and bromination of, in presence of an excess of a mineral acid, 37.
—— physiological action of, 1018.
Toluidinesulphonic acid, ortho-, action of nascent nitrous acid on, 39.
—— acids, nitro-, 502.
Toluidobenzoicacid, metanitropara-, 374.
Toluidonaphthaquinone, nitro-, 1447.
Toluidonaphthaquinoneditoluidide, 910.
Toluidotoluquinone, nitro-, 1446.
Toluphenanthrazine, bromo-, 976.
Toluquinaldine hydrochloride, ortho-, 1325.
Toluquinone, nitranilido-, 1446.

Toluylamide, ortho-, reduction of, Trans., 957.
Toluylchlorisoquinoline, 3 : 1-meta-, 625.
Toluylene semiurethane, 1125.
Toluyleneamidinebenzenylorthocarboxylic acid, 969.
Toluylene-blue, 1114.
Toluylenecarbamide, bromo-, 975.
Toluylenediamine, bromo-, 970.
Toluylenediorthotolylamidine, amido-, 371.
Toluylenediurethane, 1124.
Toluylene-red, 1114.
Toluyleneurethane, 1124.
Toluyloxamic acid, amido-, 1125.
Tolyl benzyl ketone, para-, bromoderivatives of, 260.
—— —— —— —— oxidation of, 260.
—— dibromomethyl ketone, para-, 769.
—— ethylxanthates, ortho-, meta-, and para-, 603.
—— methyl acetoxime, para-, 769.
—— —— ketone, 769.
—— —— pinacone, para-, 769.
—— phenyl ketone, para-, stereochemically isomeric oximes of, 1273.
—— phenylcarbamate, ortho- and para-, 760.
—— symmetrical dithiocarbonate, para-, 603.
—— thiocyanate, ortho-, 750.
—— thiocyanate, para-, preparation of, 749.
Tolybenzyloxythiocarbamide, ortho-, 1127.
Tolylcyanamide, ortho-, 1127.
Tolyldihydroquinazoline, para-, 73.
Tolyldihydroquinazoline, ortho-, 74.
Tolyldiphenylpyrroline, ortho-, 263.
Tolyldiphenylpyrrolinecarboxylic acid, ortho- and para-, 263.
Tolylenecarbamide, 760.
Tolylglycin, ortho-, 1285.
Tolylglycin, para-, derivatives of, 1284.
Tolylglycinimide, para-, 1284.
Tolylglyoxal hydrate, para-, 52.
Tolylhydroxythiocarbamide, ortho-, 1126.
Tolylimidodiacetic acid, ortho-, 1285.
Tolylimidodiacetic acid, para-, 1285.
Tolylketodihydroquinazoline, para-, 73.
Tolylketone aldehyde, 769.
Tolylmethylpropylene-ψ-thiocarbamide, ortho-, 160.
Tolylmethylpyrazoloneketoparatolylhydrazone, para-, 29.
Tolylorthobenzylenediamine, para-, 1258.
Tolylparatoluidide, para-, 759.
Tolylparatolyldichlorodiketoparadiazine, ortho-, 526.
Tolylparatolyldiketodihydroparadiazine, ortho-, 270.
Tolylphenyl-αγ-diketopiperazine, para-, 1284.
Tolylphenylketoxime, para-, 503.
Tolylphenylsemithiocarbazide, ortho-, Trans., 258.
Tolylpropylene-ψ-thiocarbamide, ortho-, 160.
Tolylrosinduline, para-, 909.
Tolylsulphonepropionic acid, α-para-, 382.
Tolyltetrahydroquinazoline, para-, 73.
Tourmalin-bearing copper ores from Chili, 114.
Translocation, diastase of, Trans., 509.
Transpiration and assimilation, relation between the, produced by chlorophyll, 190.
Triacetonetrisulphone, 26.
Triacetylbrazileïn, dibromo-, 997.
Triacetyldiamido-β-naphthol, 1424.
Triacetylmoradin, 405.
Trianilidobenzene, bromotrinitro-, 982.
Trianilidonaphthalene, 911.
Triazine-derivatives, synthesis of, Trans., 328.
Tribenzoyldiamido-β-naphthol, 1424.
Tribenzoyltriamidobenzene, 370.
Tribenzylphosphine, 767.
Tribenzylphosphine oxide, identity of Hofmann's dibenzylphosphine with, 492.
Tributylbenzene, tertiary, 1297.
Tricarballylamide, 134.
Tricarballylanilide, 133.
Tricarballylates, 480.
Tricarballylic acid, 183.
—— —— dibromo-, 594.
—— —— Guinochet's isomeric, 595.
—— —— isomeride of, 238.
—— acids, attempts to prepare alkyl-substituted, 747.
—— chloride, 133.
Tricarbanilidohydroxyhydrazobenzene, 615.
Tricarbanilidophloroglucinol, 500.
Tricyanides, 1252.
Tridecylquinoline, [2′-], 1234.
Tridymite, 1070.
—— expansion of, 1371.
—— synthesis of, 112.
Triethyl tricyanide, 726.
Triethylamine and ethyl iodide, effect of various solvents on the velocity of reaction between, 1366.
Triethylbenzylammonium chloride and hydroxide, action of heat on, Trans., 781.
Triethylmethylammonium chloride and hydroxide, action of heat on, Trans., 779.

Triethylorcinol ethyl ether, secondary-tertiary, 1405,
—— secondary-tertiary-, 1405.
Triethylresorcinol ethyl ether, secondary, 1404.
—— secondary tertiary, 1404.
Triethylthiocarbamide salts, 1241.
Trihydroxytritolylethanes, 1140.
Triketohexamethylene, hexabromo-, 1109.
Triketopiperazines, attempts to prepare, 1164.
Trimethyl tricarballylate, 133.
Trimethylacetamidehydroxime, 1388.
Trimethylacetic acid, action of bromine on, 1096.
Trimethylallylammonium chloride and hydroxide, action of heat on, Trans., 776.
Trimethylamine, action of, on ethyl bromisovalerate, 956.
—— compound of, with acetic acid, 1156.
Trimethylanthracene, [1 : 2 : 4-], 512.
Trimethylanthracene, [3 : 1′ : 3′-], 513.
Trimethylanthracylene, 512.
Trimethylanthraquinone, [1 : 2 : 4-], 512.
—— dinitro-, 513.
Trimethylanthraquinone, [2 : 1′ : 4′], 513.
Trimethylanthraquinone, [3 : 1′ : 3′], 514.
Trimethylanthraquinones, nitro-1 : 2 : 4-, 513.
Trimethylbenzoic acid, [2 : 4 : 5-], 981.
Trimethylbenzoic acid, [2 : 4 : 6-], 981.
Trimethylbenzylammonium chloride and hydroxide, action of heat on, Trans., 778.
Trimethyldihydroquinoline, 1292, 1421.
Trimethylene bromide, action of, on ethyl sodethylacetoacetate, Trans., 30.
—— iodide and aniline, reaction of, 1164.
—— mercaptan, 949.
—— selenide, 950.
—— selenocyanate, 959.
—— sulphide, 949.
—— tetrasulphide, 1093.
—— thiocyanate, 949.
Trimethylene-ψ-carbamide, 473.
Trimethylenediamine, derivatives of, 976.
Trimethylenedicarboxylic acid, 736.
Trimethylenephenylcarbamide, 977.
Trimethylenephenyldiamine, 977.
—— and its derivatives, 1244.
—— trimethylenephenylthiocarbamate, 1244.
Trimethylenephenylthiocarbamide, 977.
Trimethylenepseudocarbamide, 1090.
Trimethylenepseudothiocarbamide, 1090.
Trimethylene-ψ-selenocarbamide hydrobromide, 880.
Trimethylenetetracarboxylic acid, 879.
Trimethylene-ψ-thiocarbamide, 473.
Trimethylenetricarboxylic acid, symmetrical, 1397.
Trimethylenetriphenyldithiocarbamide, 977.
Trimethylenetrisulphone, 478.
Trimethylenimine, 1394.
Trimethylethylammonium chloride, action of heat on, Trans., 768.
Trimethylethylidenelactic acid, 237.
Trimethyl-2′-ethylquinoline, [1 : 3 : 3′-], 1326.
Trimethylglutaric acid, 480.
—— anhydride, 480.
—— —— α-bromo-, 480.
Trimethylisoamylammonium chloride and hydroxide, action of heat on, Trans., 774.
Trimethylisobutylammonium chloride and hydroxide, action of heat on, Trans., 773.
Trimethylisopropylammonium chloride and hydroxide, action of heat on, Trans., 772.
Trimethylphenylacetamide, [2 : 4 : 5-], 981.
Trimethylphenylacetamide, [2 : 4 : 6-], 981.
Trimethylphenylacetic acid, [2 : 4 : 5-], 981.
Trimethylphenylacetic acid, [2 : 4 : 6-], 981.
Trimethylphenylammonium chloride and hydroxide, action of heat on, Trans., 777.
Trimethylphenylglyoxylic acid, [2 : 4 : 5-], 981.
Trimethylphenylmethane, 1296.
Trimethylphenylrosinduline, 909.
Trimethylpropylammonium chloride and hydroxide, action of heat on, Trans., 771.
Trimethylpyrrolidine, [1 : 2 : 5-], 1001].
Trimethylpyruvic acid, 237.
Trimethylquinoline, [3 : 2′ : 3′-], 1326.
Trimethylsuccinic acid, 743, 1099.
Trimethylsulphine cyanide, 881.
Trimethylthiazole, 1238.
Trimethyltrimethineammonium bromide, 357.
Trimethyluracil, 31.
Triparatoluidonaphthalene, 910.
Triphenodioxazine, formation of, 490.
Triphenyl phosphite, 34.
—— thiophosphate, 35.
Triphenylamidobenzene, 614.
Triphenylamine, amido-, and nitro-derivatives of, 1409.
Triphenylaminetrisulphonic acid, 1410.

Triphenylbenzene, 1423.
—— tetramido-, 1423.
—— tetranitro-, 1423.
Triphenylbenzenedisulphonic acid, 1424.
Triphenylbiguanide, 1126.
Triphenylbutyrolactone, Trans., 680.
Triphenylcarbinol, paramido-, 1141, 1142.
—— paranitro-, 1141.
Triphenylchlorofurfuran, reduction of, Trans., 674.
Triphenylcrotolactone, Trans., 678.
—— action of bromine on, Trans., 678.
—— action of potash on, Trans., 680.
—— crystallography of, Trans., 716.
—— oxidation of, Trans., 679.
—— reduction of, Trans., 679.
Triphenyldicarbimide, 1125.
Triphenylfurfuran, Trans., 645.
—— reduction of, Trans., 675.
—— oxidation of, Trans., 675.
—— tribromo-, Trans., 713.
Triphenylguanylthiocarbamide and dicyanodiamide, 1125.
Triphenyl-γ-hydroxybutyric acid, Trans., 680.
Triphenylmethane, oxidation of, 168.
—— paramido-, 1141.
—— paranitro-, 1141.
Triphenylphosphoryl dichloride, 35.
Triphenylpyrazole, Trans., 710.
Triphenylpyrroline, Trans., 645.
Triphenylpyrrolone, Trans., 694.
—— crystallography of, Trans., 720.
—— reduction of, Trans., 695.
Triphenylsulphonepropane, 988.
Triphenylthiammeline, 1126.
Triphenylthiophen, Trans., 647.
Trisulphones, 35.
Trithioacetonedisulphone, 26.
Trithioaldehydes, α- and β-, 25.
Trithioaldehydesulphone, 26.
Triticin, molecular weight of, 227.
Tritolylbenzene, 769.
—— tribromo-, 770.
—— trinitro-, 770.
Trona, 340.
Tropic acids, optically active, formation of, 74.
Tropidine, conversion of, into tropine, 1167, 1333.
Tropine, conversion of tropidine into, 1167, 1333.
Tropinic acid, properties and salts of, 1449.
Truffles, chemistry of, 659, 821.
Truxene-derivatives, 514.
Truxillic acids, theory of the, 1424.
Truxone-derivatives, 514.
Tryptophan, 804.
Tuberculosis, udder, changes in milk by, 652.
Tubes, sealing, under pressure, 941.
Tungsten, estimation of, in metallic tungsten, 420.
—— influence of, on steel, 567.
—— oxide, influence of, on the decomposition of potassium chlorate, Trans., 276.
Tungstic acid and vanadic acids, separation of, 666.
—— —— colloïdal, molecular weight of, 1215.
Tungstovanadates, 1066.
Tunicin, heat of combustion of, 938.
Turanose, 733.
Turpentine, estimation of petroleum in, 669.
—— French essence of, adulteration of, 422.
—— ordinary, detection of, in Venice turpentine, 307.
—— oxidation of, in sunlight, Proc., 1890, 99.
—— production of camphor from, Trans., 961.
Turpentineglycuronic acid, 1287.
Typhotoxine, Brieger's, 391.
Tyrolite from Utah, 853.
Tyrosine ethyl ether, behaviour of, in animal metabolism, 187.
—— heats of combustion and formation of, 936.

U.

Ulexine, 180.
Umbelliferone methyl ether, oximido-, 624.
—— —— —— thio-, 624.
Undecylacetylmelitriose, 1085.
Uracil, nitro-, alkyl derivatives of, 31, 32.
Uramidocinnamic acid, ortho-, 1123.
—— —— orthothio-, 1123.
Uraninite, nitrogen from, 456.
Uranium and thorium, new case of isomorphism of, 15.
—— carbonylferrocyanide, 117.
—— oxide, influence of, on the decomposition of potassium chlorate, Trans., 276.
—— phosphates, 1056.
—— sulphate, 15.
Uranyl chromate and its double salts, 852.
Urao, or native soda, 340.
Urea, estimation of, 308, 931.
—— formation of, in the dog-fish, 1451.
—— heats of formation and combustion of, 206.
—— origin of, in the animal economy, 184.

Urea See also Carbamide.
Uric acid, ammoniacal fermentation of, 1399.
—— —— estimation of, in human urine, 1345.
—— —— estimation of, in urine, 670.
—— —— heat of formation of, 1040.
—— —— in urine, 540.
—— —— influence of sodium phosphate on the excretion of, 397.
—— —— origin of, in mammals, 184.
—— —— the Fokker-Salkowski method of estimating, in normal and pathological urines, 304.
Urimidosuccinic acids, molecular weights of, 725.
Urine, analysis of, 1199.
—— benzamide in, after administration of benzaldehyde, 188.
—— cystin in the, 1018.
—— detection of sugar in, 427.
—— detection of thiosulphuric acid, 812.
—— dog's, nitrogenous constituents of, 279.
—— estimation of albumin in, 1199.
—— estimation of sugar in, by fermentation, 836.
—— estimation of the potassium in, as hydrogen potassium tartrate, 187.
—— estimation of total phosphorus in, 825.
—— estimation of uric acid in, 670.
—— healthy, absence of acetone in, 399.
—— human, estimation of uric acid in, 1345.
—— —— nitrogenous constituents of, 280.
—— normal, ethyl carbamate in the alcoholic extract of, 654.
—— occurrence and detection of indigo-red in, 1032.
—— of the horse, chemistry of, 914.
—— precipitation of albuminoids from, 273.
—— proteïds in, 1174.
—— reducing substances in, 188, 279.
—— substances likely to be mistaken for sugar in, 279.
—— the phenylhydrazine test for sugar in, 835.
—— uric acid in, 540.
Urines, normal and pathological, estimation of uric acid in, 304.
Urobilin in the bile, 187.
Uroleucic acid and alcaptonuria, 188.
Urtica urens, *U. dioïca*, and *U. pilulifera*, constituents of, 545.

V.

Vacuum joints and taps, TRANS., 958.
Valency, lecture experiment for the demonstration of, 1050.
Valeraldehyde and succinic acid, condensation of, 590.
—— and pyrotartaric acid, condensation of, 591.
Valeric acid, γ-bromo-, 585.
—— —— dibromo-, 585.
Valerolactone, action of sodium ethoxide on, 867.
Vanadic acid and tungstic acids, separation of, 666.
—— —— preparation of, 16.
—— —— separation of, from phosphoric acid, 1343.
—— anhydride, compound of, with sulphuric acid, 336.
—— —— influence of, on the decomposition of potassium chlorate, TRANS., 276.
Vanadium arsenate, 1380.
—— estimation of, 1343.
—— fluorine compounds of, 15.
—— in potassium hydroxide, 706.
—— oxyfluorides, compounds of metallic fluorides with, 15.
Vanadoarsenates, 1380.
Vanadotungstates, 1066.
Vanillin from *Rosa canina*, 1270.
Van't Hoff's theory, deductions from, 845, 1205.
Vaporisation, heat of, determination of, by means of the steam calorimeter, 1040.
Vapour-densities of selenium chlorides, 558.
—— —— of substances below their boiling points, determination of, 440.
—— density apparatus, Hofmann's, trough for, 681.
—— —— determination of, 681, 1042.
—— —— determinations, 1365.
—— —— determinations under reduced pressure, apparatus for, 101.
—— —— of antimony pentachloride, 16.
—— pressure of aqueous solutions, 323.
—— —— reductions, determination of molecular weight from, 323.
—— pressures of solutions, determination of, 1364.
—— —— of solutions in acetic acid, 554.
Vegetable cell-membrane, composition of, 1457.
Velocity of reaction, influence of glass surfaces on, 1208.
Veratrine, action of alcoholic potash on, 1448.

Veratrine, action of hydrochloric acid on, 1449.
—— bromides of, 1448.
—— crystallised, 1448.
—— dry distillation of, 1449.
—— oxidation of, 1449.
Vesuvian, composition of, 221.
Vinegar, estimation of tartaric acid in, 428.
Vinyl alcohol, a constant constituent of ethyl ether, 118.
—— oxymercurochloride, 118.
Vinylpiperidine, 68.
Vinylpyridine, 67.
Viscosity of liquids, 441.
Vitellin, heat of combustion of, 938.
Vivianite from the Szentes artesian well, 714.
Voltaic cell, Clark, standard, 202.
—— —— silver-mercury, and its relation to temperature, 550.
—— —— theory of 314.
—— cells, electromotive forces of, containing mixed salt solutions, 202.
—— energy of aqueous solutions, 941.
—— —— of dissolved chemical compounds, 317.
Volume, change of, on dissolving salts in water, 844.
—— molecular, of organic compounds, formulæ for calculating, 323.
—— —— law of, 1043.
—— pressure and temperature, relation of, in the case of liquids, 321.
—— specific, of aqueous vapour, 207.
—— —— of phosphorus, Trans., 562.
Volumes, molecular, of aromatic compounds, 683.

W.

Wads, 570.
Water, action of chlorine on, in the light, Trans., 613.
—— analysis, 196, 667.
—— —— statement of results of, 196.
—— and hydrogen chloride, simultaneous synthesis of, 8.
—— composition of, 330.
—— dissociation of salts containing, 206.
—— distilled, electrical conductivity of, 1357.
—— estimation of alkalis in, 299.
—— estimation of chlorine, 86.
—— estimation of dissolved oxygen in, Trans., 185.
—— estimation of free oxygen in, 412.
—— estimation of, in air, 1188.
—— estimation of, in soils, 832.
—— estimation of, in salts, 417.
Water, estimation of iron in, 419.
—— estimation of nitrates and nitrites in, Trans., 811.
—— estimation of the hardness of, 86.
—— examination of, for technical purposes, 298.
—— fresh and sea, solubility of calcium carbonate in, 450.
—— from the Roundwood colliery, 222.
—— of crystallisation, 1209.
—— ordinary, copper precipitate formed in, 851.
—— penetrability of glass by, 691, 692.
—— sea-, solubility of some substances in, 719.
—— specific inductive capacity of, 203.
Waters, drainage, 1459.
—— manganiferous spring, 854.
—— mineral, of Cransac, 1385.
—— mineral, of Malaisie, 1081.
—— potable, colorimetric methods of estimating nitrates in, 831, 832.
—— —— containing magnesium, estimation of carbonic anhydride in, 197.
Wax, examination of, 429.
Weldon mud, gas-volumetric estimation of, 1470.
Whale, bottle-nosed, milk of, 812.
Wheat in the experimental plots at Grignon in 1889, 820.
—— ungerminated, diastatic ferment of, 650.
Wheat-meal and -bran, detection of rye-meal and -bran in, 302.
—— —— nutritive value of, 396.
Wheat-straw, composition of, 1461.
Wiluite, 220.
Wine, detection of alkanna red in, 311.
—— detection of salicylic acid in, 1475.
—— estimation of glycerol in, 426.
—— estimation of potassium hydrogen tartrate, tartaric acid, and malic acid in, 427.
—— statistics of Germany, 285.
—— lees, valuation of, 303.
Wines, bouquets of, 1180.
—— colouring matters of, 311.
—— detection and estimation of lactic and butyric acids in, 1344.
—— influence of yeast on the bouquet of, 281.
—— raisin and grape, method of distinguishing between, 1031.
—— raisin, and their richness in nitrogen, 1031.
—— sweet, polariscopic estimation of sugar in, 426.
—— volumetric estimation of tannin in, 431.
Winter bark, true, 405.
Winterene, 405.
Wintergreen oil, 256.

Wohlerite, 1079.
Wolframite, analysis of, 1027.
—— method for the analysis of, 420.
Wollastonite, artificial preparation of, 18, 220.
Wood, products formed in the distillation of, 956.
Wood-fibre, estimation of, in paper, 670.
Wood-gum, from straw, &c., 472.
Wool, heat of combustion of, 938.
—— thermochemistry of, 939.
Wool-oils, analysis of, 305.
Work, Berthelot's law of maximum, and spontaneous endothermic reactions, 681.
—— respiration in the horse during, 1170.
—— muscular, influence of, on the exhalation of carbonic anhydride, 1334.
Worms, entozoic, respiration of, 274.

X.

Xanthone, tribromo-, 893.
Xanthoxylon Senegalense, bark of, 918.
Xenotime from South Norway, 1078.
Xylalphthalide, 625.
—— nitro-, 625.
Xylalpthalimidine, meta-, 625.
—— nitro-, 625.
Xylalphthalalnitronitrite, 625.
Xylene, dibromodichloro-, 1248.
—— dibromopara-, preparation and properties of, TRANS., 974.
—— 4 : 6-dichlorometa-, 1106.
—— —— amido-, bromo-, and nitro-derivatives of, 1247.
—— —— orientation of, 1246.
—— diiodo-, 1107.
—— dinitrodichloro-, 1248.
—— dinitroso-, 607.
—— iodometa-, action of sulphuric acid on, 1106.
—— meta-, chlorine substitution products of, 1105.
—— tetrachlorometa-, 1106, 1248.
—— trichlorometa-, 1106.
Xylenecarboxylic acid, nitronitrosometa-, 980.
—— —— dinitrosometa-, 980.
Xylenes, dibromo- and dichloro-, and their transformation by means of sulphuric acid, 1247.
Xylenesulphonamide, dibromopara-, 977.
—— —— reduction of, TRANS., 979.
Xylenesulphonic acid, dibromopara-, TRANS., 976.
—— acids, para-, TRANS., 974.
—— chloride, dibromopara-, TRANS., 977.
Xylenol, paranitroso-, 607.
Xylenylamidoxime and its derivatives, 49.
Xylenylbenzenylamidoxime, 49.
Xylenylcarbonylamidoxime, 50.
Xylenylethenylazoxime, 50.
Xylenylphenylthiouramidoxime, 50.
Xylenylphenyluramidoxime, 50.
Xylenyluramidoxime, 50.
Xylidine, para-, 606.
Xyloquinol, dichlorometa-, 1247.
Xyloquinone, dichlorometa-, 1247.
Xyloquinonedioxime, para-, 607.
Xylose from straw, &c., 472.
—— from straw-gum, 1460.
—— heats of combustion and formation of, 1360.
Xylosecarboxylic acid, 1399.
Xylyl ethylxanthate, meta-, 603.
Xylyl methyl ketone, 3 : 5-dinitro-, 981.
—— —— —— 5-amidometa- and 5-nitrometa-, 980.
—— —— —— 3-nitrometa-, 980.
Xylyl methyl ketone, ortho-, 770.
Xylyl nitrosomethyl ketone, 3 : 5-dinitro-, 981.
Xylylacetic acid, meta-, 499.
Xylylamide, meta-, 975.
Xylylamides, ortho- and meta-, 158.
Xylylanilide, 759.
Xylyldiphenylpyrroline, meta-, 263.
Xylylene sulphides, 134.
Xylylglycollic acid, meta-, 499.
Xylylglyoxylic acid, dinitrometa-, 980.
—— —— dinitrosometa-, 979.
Xylylhydrazine, meta-, 1410.
Xylylhydrazinesulphonic acid, sodium salt of, 1410.
Xylylmalonanilide, meta-, 499.
Xylylmalonic acid, meta-, 498.
Xylylmethylcarbinol, meta-, 979.
Xylylmethylcarbinol, ortho-, 770.
Xylylmethylsulphine iodide, ortho-, 135.
Xylylphenylacetoximeorthocarboxylic acid, oximidolactone of, 625.
Xylyltartronic acid, meta-, 499.

Y.

Yeast, alcoholic extract of, 905.
—— elliptical, effect of copper salts on, 814.
—— influence of, on the bouquet of wines, 281.
—— liquefaction of, TRANS., 869.

Yeast liquor, composition of, TRANS., 878.
Yeast-albuminoïd, TRANS., 886, 893.
Yeasts, wine, preparation of, 1179.
Yew tree, alkaloïd of, 650.
Yolk of egg, detection of the colouring matter of, 840.
—— —— heat of combustion of, 938.
Yttria, action of magnesium on, 693.
—— minerals from Llano Co., Texas, 457.
—— nature of, 566.
Yttrialite, 458.
Yttrium earths, 851.
—— phosphate from South Norway, 111.

Z.

Z_α and Z_β, nature of, 566.
—— —— new fluorescences of, 435.
Zeolites, composition of, 717.
Zinc, action of, on dilute sulphuric acid, TRANS., 815.
—— and copper sulphates, electrolysis of a mixed solution of, 678
—— and mercury, double cyanides of, 855.
—— —— interaction of the haloïd salts of, 224.
—— antimonate, 216.
—— arsenate, 563.
—— —— crystalline anhydrous, 214.
—— cyanide, action of cupric salts on, 464.
—— dust, valuation of, 1190.
Zinc, effect of, on the freezing point of tin, TRANS., 382.
—— electrolytic estimation of, 294.
—— electrolytic separation of mercury and of silver from, 664.
—— estimation of, in blende containing manganese, 827.
—— estimation of, in calamine, 418.
—— estimation of, in iron ores, 1192.
—— estimation of, in its ores, 1191.
—— estimation of, in manganiferous flue deposits, 294.
—— estimation of, in presence of iron and manganese, 1193.
—— ethoxide, non-existence of, 482.
—— ethyl, action of oxygen on, 481.
—— hydrosulphide, 214.
—— lead, and tin, alloys of, 336.
—— oxide, action of magnesium on, 452.
—— phosphate, crystalline anhydrous, 214.
—— potassium arsenates, 563.
—— separation of, from nickel, 418.
—— sodium arsenates, 563.
—— —— thiosulphate, 12.
—— volumetric estimation of, 196, 1191.
Zinc-ammonium compounds, 452.
Zinciferous clays from South West Missouri, 573.
Zirconia, crystallisation of, 1071.
Zirconium, atomic weight of, 705.
—— dioxide, action of magnesium on, 1375.
Zuiderzee, composition of the sea mud in the new alluvia of the, 822.
Zymolysis, 538.

ERRATA.

VOL. XLVIII (1885).
